NEXT ANNUAL MEETING, NEW YORK CITY, APRIL 27-28-29, 1936

Published twice a month by the MEDICAL SOCIETY OF THE STATE OF NEW YORK Office of Publication 100 State St., Albany, N. Y.

Executive and Editorial Offices at 33 West 42nd St., New York, N. Y. Telephone CHickering 4-5570

Intered as second class matter June 15, 1934, at the Post Office at Albany, N Y, under the Act of March 3, 1879 Acceptance for mailing at special rate of postage provided for in Section 1103, Act of October 3, 1917, authorized on July 8, 1918 Copyright, 1935, by the Medical Society of the State of New York.

THE ALKALINE EFFECT OF MILK

OODS containing salts of the akaline metals generally exert an alkaline effect in the body. Because of its calcium and potassium salts content, milk is definitely in this class. These salts are largely "burned" in the body following the ingestion of milk. In this process of reduction, the original acid parts of the salts are eliminated in the breath . . . the metals remain as an alkaline ash for neutralizing acidic products in the blood. Increased ingestion of milk would tend, therefore, to increase the alkaline ash content (or alkaline reserve) of the blood.

THE STATE OF NEW YORK

DAIRYLEA *Vitamin D* MILK

OU, as a physician, know that sunshine is the best natural source of Vitamin D. But at this time of year the ultra violet rays of sunlight reach minimum intensity. And these weak ultra violet rays are further reduced by clouds, dust, smoke, buildings and clothing.

To provide this important vitamin -to help maintain the health and promote the growth of your patient, recommend Dairy lea Vitamin D Milk, particularly during the winter months. Taken in normal amounts this milk contains adequate Vitamin D for proper nourishment of the bones and teetli. This carefully guarded milk forms the ideal vehicle for Vitamin D because it provides the desired simultaneous ingestion of calcium and phosphorus and Vitamin D.

Dairylea Vitamin D Milk is your assurance of a pleasant, safe and economical method of giving your patients this executial combination of food and health elements.

This seal shows that our Vitamin D Milk and all advertising claims for it have been

accepted by the Committee on Foods of the American Medical Association.

Produced by

THE DAIRYMEN'S LEAGUE CO-OPERATIVE ASSOCIATION, INC.

Our Illenne: We, the farmers of the Dairymen's League, recognize a definite obligation to the public. Since milk is nature's most nearly perfect food, we pledge ourselves, in the production of Dairylea Milk Products, to do everything within our power to safeguard their purity and quality.

AIRYLEA MILK

IN BUFFALO DAIRYLEA MILK IS SOLD UNDER THE TRADE NAME, WECKERLE.

ACID RESISTANCE

WITH

KALAK

Hypertonic - Alkaline - Carbonated - Not Laxative

The years of experience with physicians who have used Kalak show that the use of a formula containing calcium, magnesium, sodium and potassium salts represents a correctly balanced solution. This is Kalak which, as such, aids in maintaining a balanced base reserve.

How Alkaline Is Kalak?

One liter of Kalak requires more than 700 cc. N/10 HCl for neutralization of bases present as bicarbonates. Kalak is capable of neutralizing approximately three-quarters its volume of decinormal hydrochloric acid.

Preserve the Advertising Pages for Reference

Enterprising physicians who read this JOURNAL, file away scientific articles which may be of value to them in their practice. A year hence, two years, five years, some article may be precisely what is needed.

What is true of the value of the scientific article is equally true of advertisements. Remember that if these advertisements were not of service and benefit to the medical profession, they would not be here. You may need the information in any one of them at any time. Keep them. They will be of service to you.

Next month, next year, you may wish to use one of the advertised medical preparations or surgical appliances. You may wish to send a patient to a special hospital, spa, sanitarium, or on a cruise for rest and health. You may wish to know about hotels, steamers, railways. Keep the advertising pages and save time, trouble, uncertainty.

IMPROVED ANTITOXINS

IOLOBULINI Lederle HODITED

DIPHTHERIA . . . SCARLIT FEVER
ERYSIPELAS . . . STAPHYLOCOCCUS

GAS GANGRENE . . TETANUS

- · 40% less bulk!
- · lower riscosity!
- more of the troublesome proteins discarded and the remainder modified AND HENCE
- fewer reactions!
 Now being supplied on all orders

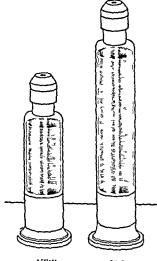

This REDUCTION IN BULK of our new Globulin Modified Antitoxins is fairly typified in the illustration of the Tetanus syringes.

Reduction of serum sickness follows, as is to be expected from the reduced bulk and the lessened amount of trouble-some and uscless proteins.

The modification of the globulins, it is believed, further contributes toward reduced liability to elicit serum sickness.

When Your Patients Need Sunlight—

• "Florida and lots of sunshine for you."—That's what you would like to say many a time to certain of your patients. But you know it can't be done. Money ... business ... family ties ... and other obstacles stand in the patient's way. What is the alternative?

The only logical alternative is a sun lamp in the home, where the patient can get his daily quota of sunlight without having to go away.

• Carbon arc lamps produce the closest duplication of natural sunlight of any artificial source of energy according to the U. S. Bureau of Standards. They produce a complete spectrum including visible light, infrared and ultra violet rays. They are priced from \$6.95 up to \$39.50. Cold Quartz lamps are available as low as \$50.00.

Wherever sunlight is indicated we have a lamp that you can recommend at a price your patient can afford to pay.

Write or phone for complete information on our low priced efficient sun lamps to

The Newest Idea In Adhesive Tape Technique

The gentle removal of adhesive tape with ADHESOL is receiving an enthusiastic welcome by physicians everywhere. Developed for the express purpose of removing adhesive tape and plasters, its action eliminates the need for ripping with resulting possibility of causing a new source of infection. ADHESOL acts quickly—without pulling—without pain, and eliminates irritation or discomfort to the patient. ADHESOL has a pleasant odor which disappears instantly and leaves the skin clean, soft and free of all gum or stickiness. Far superior to any other product designed for this purpose, the appearance of ADHESOL on your cabinet is a mark of prestige. Try it! All leading surgical supply houses can furnish you with ADHESOL, or send the coupon for a regular professional size trial bottle.

CORRECT unbalanced diets NATURALLY

Contributing to the correction of the typical starch-drenched, sugar-loaded, mineral deficient, unbalanced dicts—JUICE-O-VEG offers the medical profession a more natural means of improving regular or special diets of children and adults. JUICE-O-VEG is a scientifically combined extract of fresh vegetables and fruits, and simply the pure raw juices pressed from these staple foods through an especially developed machine. Made under the personal formula and supervision of its creator, Constant C. Foltis, president of the well-known Foltis Fischer Restaurant System, JUICE-O-VEG is the product of experience backed by years of study and practice in combining foods rich in elements beneficial nutritively.

THE CANNING PROCEDURE

• Some misunderstandings exist as to the mechanics of the commercial canning procedures. Although some such information is available (1) (2), it is not surprising that the facts are not more generally known. The art of canning has been largely developed by, and retained within, the industry.

Of necessity, canning procedures vary with the product packed. However, it is possible to indicate in broad detail the treatment to which foods may be subjected during canning.

Cleansing Operations

Raw materials are given a thorough water cleansing, usually by washing under high pressure sprays.

Preparatory Operations

Following washing, undesirable stock is removed by sorting, trimming, peeling and coring operations, as occasion may demand. With some products these operations are performed mechanically.

Blanching

Certain products are "blanched" or scalded by immersion in hot water. This process serves not only to clean the product further, but also to soften the tissues and expel air therefrom.

Preheating and Filling Operations Here practice varies with the product. Sometimes the food is precooked and filled into cans; again, it may be filled into cans and hot water or hot salt and/or sugar solutions added; still again, the filled cans are "exhausted" in a steam or hot water box. All these operations, the majority of which are mechanically performed, serve to preheat the product and exclude air from the cans.

Sealing, Processing and Cooling Operations

The filled cans are hermetically sealed on an automatic "closing" machine while the contents are still hot; the sealed cans are then heat processed to destroy spoilage micro-organisms; finally, the cans are cooled in water or air. Cooling contracts the contents and produces a vacuum within the can.

Such are the broad details of the canning procedure. We trust this brief word picture will bring better understanding of the treatments to which canned foods are subjected.

230 Park Avenue, New York City

(1) 1924, Commercial Fruit and Vegetable Products, W. C. Cruess, McGraw-Hill, New York (2) 1924, A complete Course in Canning, The Canning Trade, Baltimore

This is the eighth in a series of monthly articles, which will summarize, for your convenience, the conclusions about canned foods which authorities in nutritional research have reached. We want to make this series valuable to you, and so we ask your help. Will you tell us on a post card addressed to the American Can Company, New York, N. Y., what phases of canned foods knowledge are of greatest interest to you? Your suggestions will determine the subject matter of future articles.

The Seal of Acceptance denotes that the statements in this advertisement are acceptable to the Committee on Foods of the American Medical Association.

Physicians who have visited the laboratories in which Petrolagar is made have often expressed surprise at the unusual precautions taken to assure accuracy in the manufacture of this most palatable mineral oil emulsion. Here, in the home of Petrolagar, is to be found every practical scientific instrument obtainable for the purpose of testing and retesting raw materials and the finished product . Most important, however, in the preparation of this fine pharmaceutical, are the human minds and hands that direct and use the instruments provided in the Petrolagar

control laboratories. Minds trained in the best universities and hands skilled in the techniques essential to accomplishment-enable us to cooperate with physicians in the successful treatment of constipation.

Petrolagar Laboratories, Inc. Chicago

Petrolagar is a mechanical emulsion of pure mineral oil (65% by volume) and agar-agar. prepared in Five Types for the treatment of constipation. no compromise with fads—
"see physician"

We have seen foot fads and shoe fads come and go by the score—but we have known that the physician represents a continuous command of foot science. So, we have let the fads "have their little day" and spent our years, now 21 (we are of age), in advising, "See physician first, then see us." Working together, we have developed your-and-our professionally counselled Special Infants' Shoes, Invertor-Adductor, Club Foot, Semi-Corrective, Special and Regular Orthopedic Shoes. Time to Collect

"DOLLARS"

"Dollars" have two values—an intangible one that varies according to the personal wealth of its possessor, and a purchasing power which fluctuates with the trend of business and employment.

The loss of not having "money due" collected and working for you, is but a small matter compared with the drop in purchasing power through sharp rises in the cost of living. Besides discounting your original fee exorbitantly, past due accounts become even more difficult to collect because the same rise in living costs generally effects your patients' ability to meet the obligation.

It is easy to see that your \$100 fee of last month may actually be worth only \$50 if its payment lapses six months or a year, not to mention the equally great possibility of its never being paid.

Having no "Aladdin's power" we cannot guarantee collections when too great a delay has been permitted, but we have been unusually successful on accounts that begin to be annoying and doubtful to the creditor. We can do as much for you.

* A bond has been deposited with the Treasurer of the Medical Society of the State of New York to protect its members against misuse of money collected from their patients.

BORJOM IS

... natural carbonated alkaline mineral water, differing from other mineral waters in the presence of bromide and iodide salts, and in its tasteful, natural carbonization.

BORJOM is bottled at the famous Katherine Spring in the Caucasus, Russia, known and valued for exceptional medicinal qualities, recommended for cases of gastric hyperchlorhydria and of value in conditions of disturbed acid base equilibrium.

Professor Metchnikoff, Obolensky, Pletnev, Luntz, Struve, and others, since 1852, have written regarding the effects of BORJOM upon the human system, and its medicinal merits.

Chief constituents per liter of BORJOM are:

Sodium Bicarbonate		
Basic Ferric Oxide Bicarbonate		-
Magnesium Bicarbonate	0.1233	gm.
Calcium Bicarbonate · · · · · · · · · · · · · · · · · · ·	0.3659	gr.
Strontium Bicarbonate	0.009	gr.
Sodium lodine	0.0006	gm.
Sodium Bromide	0.0005	gm.
Potassium Chloride	0.0428	gm.
Silica	0.003	gm.
Free Carbonic Acid	434	c.c.

A Poor Scholar . . .

because of a Poor Breakfast

MANY a child is scolded for dullness when he should be treated for undernourishment. In hundreds of homes a "continental breakfast" of a roll and coffee is the rule. If, day after day, a child breaks the night's fast of twelve hours on this scant

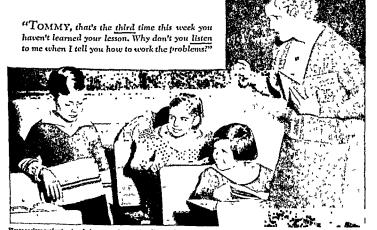

fare, small wonder that he is listless, nervous, or stupid at school.

Pablum offers a happy solution to the problem of the school-child's breakfast. Mothers who learn about Pablum from their physicians are delighted to serve it for it needs no cooking and can be prepared in a minute at the table—more quickly than many less nourishing foods. Pablum not only ends the bane of long cooking of cereals but in addition furnishes a variety of minerals (calcium, phosphorus, iron, and copper) and vitamins (A, B, G, and E) not found so abundantly in any other cereal.

PABLUM is rich in calcium and iron, minerals likely to be deficient in the school-child's diet yet needed in more than average amounts during childhood. Pablum is 6 times richer than fluid milk in calcium and contains 10 times more iron than does spinach. It also furnishes generous amounts of vitamins B and G, essential for normal appetite. Unlike other cereals, Pablum is base-forming, important because the growing child needs to store alkali. The nutritional value of Pablum is attested in studies by Crimm et al who found that tuberculous

children receiving supplements of Pablum showed greater weight-gain, greater increase in hemoglobin, and higher serum-calcium values than a control group fed farina. Reprint sent on request of physicians. Mead Johnson & Company, Evansville, Indiana, U.S.A.

Pablum (Mead's Cereal thoroughly cooked) is a pil table cereal enrienced with vitamin- and mineral-containing foods, consisting of wheatmeal, oatmeal, commeal, wheat embryo, alfalfa leaf, beef bone, brewers' yeast, iron salt, and sodium chloride.

Please enclose professional card when requesting samples of Mead Johnson products to cooperate in preventing their reaching unauthorized persons

Benzedrine Inhaler

A VOLATILE VASOCONSTRICTOR

The vapor form of Benzedrine Inhaler presents obvious advantages over liquid non-volatile vasoconstrictors.

Benzedrine Inhaler* combines VOL\-TILITY with a potency equal to or greater than that of ephedrine. Yet ephedrine-like reactions such as atony and returgescence are "so slight as to be

virtually negligible." (Scarano: Med. Record, Dec. 5, 1931.)

Fig. 1. The distribution of a liquid inhalant when applied by a dropper.

The solution does not

The solution does not reach beyond the lower border of the inferior turbunate, the bulk of the liquid gravitating to the pharynx. The spaces between the turbinates, where the congestion is greatest, have not been reached.

*Lichtubelspacked with henzyl methyl cathinamine, 325 gm, oil of lavender, 097 pm t meuthol, ,032 gm.

Fig. 2. The distribution of a hand inhalant when applied by a spray or alonizer.

The inferior turbinate intercepts the bulk of the liquid intended for the middle and upper meati, sites of greatest congestion. The excess liquid is deflicated to the roof of the hard palate, whence it reaches the pharynx.

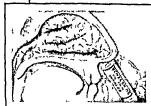

Fig. 3. The distribution of a vapor when smiled up the nose by means of an inhaler.

The vapor diffuses throughout the entire upper respiratory tract, reaching and reducing congestion wherever it exists.

PLASTIC REPARATIVE SURGERY

This course includes diagnosis and determination of treatment; pre-operative preparation; anesthesia; operative technique; dressings; postoperative care; with special reference to utilization of the skin and other lissues in correction of disfigurement and replacement of loss, congenital or acquired. Operations on the cadaver. Particular attention is given to lectures, studies and demonstrations of advances in surgical anatomy, pathology, etc., with special reference to the problem actually under consideration.

THORACIC SURGERY

An intensive course. Surgical treatment of chronic suppuration of the lung (pulmonary tuberculosis, abscess of the lung, bronchiectasis) and tumors of the lung. Surgical lesions of the esophagus, heart and diaphragm. Empyemas Witnessing of operations. cadaver operations, pathologic physiology, experimental surgery and bedside rounds. Indications for surgical treatment, pre-operative care and postoperative management.

Gentlemen, it is with pride in our profession that I tell you of my difficulty in getting clinical material to illustrate our discussion of rickets today. Twenty years ago ??

The above picture was suggested by a situation arising at a recent medical meeting attended by thousands of physicians. Their comments revealed a country-wide decrease in the incidence and severity of rickets, the result of clinical application of modern developments in the science of nutrition.

Three minims of Haliver Oil with Viosterol, in a tasteless gelatin capsule, or

delivered from a dropper, provide at least as much vitamin A and vitamin D as four teaspoonfuls of Cod-Liver Oil (minimum standards U. S. P. X revised 1934).

Parke-Davis Haliver Oil with Viosterol has a vitamin A activity of not less than 50,000 U.S.P. (1934 Revision) units per gram; and vitamin D activity of not less than 10,000 U.S.P. (1934 Revision) units per gram.

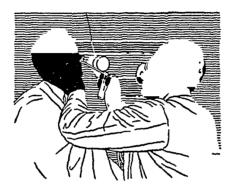

Parke-Davis Haliver Oil with Viosterol is available in 5-cc. and 50-cc. amber lottles with dropper, and in boxes of 25, 100, and 250 three-minim gelatin capsules

THE GENESIS OF RENAL CALCULI Pathological-Physiological Considerations

ALUXANDER RANDALL, M.D., F.A.C.S., Philadelphia, Pa.

When one undertakes an appreciation of the problem of the etiology of stone in the upper urinary tract, one is confronted by the fact that it appears to be increasing in its complication rather than in its simplification. Yet, when one tabulates the actual theories relative to the causation of renal calculus, it is interesting to find that, in spite of their wide divergence, they are after all rather closely interrelated. It is essential, when elucidating any complex picture, that cause be put to one side, and effect to the opposite side, and it is my effort to try to clarify this one point of cause and effect in our appreciation of stone in the upper urinary tract.

First of all, let us be cognizant of what has happened in our understanding of stone in the lower urinary tract. For centuries considered a disease entity, and operated upon with what surgeons thought success, bladder stone is now looked upon as a symptom and not a disease. There is not a surgeon but will . finish an operation for the removal of stone in the bladder by appreciating that it is a resultant effect and by looking for its cause. Prostatic obstruction, diverticulum, fistula, tumor, and ulcer are looked upon as the primary reasons for such a vesical calculus, and the prevention of its recurrence will depend upon the successful removal of the individual cause.

How often is the surgical problem of a renal calculus approached with a similar understanding of the fundamental pathology? How often, in the course of a difficult exposure, is a causal obstructive factor looked for and corrected? And how often, after the removal of a renal calculus, are steps of a prophylactic nature taken, both at the operating table and during the postoperative convalescence, to safeguard the patient against recurrence? In other words, do we approach every case of renal calculus looking upon the stone as an effect and, in each case, attempt to find a cause? And have we transported our knowledge of the causal factors of stone in the lower urinary tract to an appreciation of what must be similar causal factors in the origin of stone in the upper urinary tract? I think the time is long past due when we should cease to lecture, write papers, and even publish books under the title of "Calculus Disease," for stone in any part of the urinary tract is but a symptom and not a disease entity.

Etiology

Let me briefly review for you the five theories which are current today as reasons why a kidney becomes encumbered with a calculus, for certainly we are all agreed that there must be a basic etiology, of which the stone is but a symptom.

1. Unquestionably, priority belongs to the dietary theory. This causal factor comes to our attention from two separate angles. First, and perhaps of the greatest importance, is the realization that stone of the bladder in childhood has almost disappeared from the picture of surgery. Fifty years ago (and for the period antedating this) it was found in civilized countries as a dominant factor in "calculus disease." It has been pointed out that in England, in 1800, forty-five per cent of the cases of vesical calculus occurred in children under fourteen years

of age. In France over half of the cases of stone in Civiale's clinic were operations on patients under twenty years of age. Today this picture has so changed that in England, France, and America bladder stone in childhood is a rarity. And the only factor to which we can point, as bearing upon the disappearance of this surgical condition, has been a liberalization of the diet of childhood. Children today are fed from infancy on a diet which would have made our grandparents shudder, and this is to be compared to the picture of stone in childhood which still persists in its prevalence in the surgical clinics of the countries where the dietary is still of a variety exceedingly limited, as it used to be in Europe.

The second point under this theory has been the proof that diets deficient in vitamin A are exceedingly prolific of stone formation. The reason given is that such a diet causes certain changes in the epithelium of the urinary tract, which is termed "keratinization." Two things are significant: First, that such stones are consistently formed of calcium-magnesium phosphate, and second, that in experimental animals where stone has been so produced, such concretions have been made to disappear if the diet is changed to one rich in vitamin A. Here it seems we can clearly see cause and effect.

2. The second theory which enters this picture is that of infection. It has been said that if every case of stone were searched to its ultimate end, an infection would be found underlying it. This is probably an overstatement, but, nevertheless, infection unquestionably does play a very definite part in the formation of some stones. There are numerous instances and examples to be cited in relation to this theory, but let me recall to mind Rosenow's work and also the observation of the frequent occurrence of renal calculus in the osteomyelitis cases subsequent to war injuries.

Again, two things are of great significance as regards infection and stone: First, the frequency of infection where epithelial changes due to vitamin A deficiency predominate, and the interrelationship of these two factors: second, the role that infection frequently plays as an etiological factor in the recurrence of renal stone.

3. The third theory is the effect of stasis and faulty drainage. Long a recognized factor in the lower urinary tract, it must likewise play a definite part in the etiology of certain stones in the upper urinary tract. Stone has been frequently watched during its period of actual growth, where occlusion of ureterovesical junction or long-standing ureteral obstruction has produced faulty drainage. Stone has been found in a rela-

tively high percentage of cases where individuals have been bedridden, such as in the care of generalized disease, in the immobilization for fractured bones, and in the care of children with tuberculous lesions of the spine. All these conditions are related to faulty renal drainage and, in addition, are frequently associated with chronic infection and with the recognized decalcification of the bony skeleton, and the loss of calcium during long periods of complete muscular inactivity.

Again, let me accentuate the close interrelation of these three theories—diet, infection, and faulty drainage. It is neither a constant fact, nor it is necessary to expect that every kidney pelvis which is poorly drained, even if also infected, must form a stone. Such is quite comparable to the incidence of bladder calculus as an accompaniment of prostatic obstructions. The failure of stone development in cases where the ideal morbid set-up is waiting is one of the strongest facts that we have to face in the realization that our present theories are not sufficient.

4. Our fourth theory is that fascinating one of disturbance in the colloidal mechanism of the urine which plays a very important role in the body's ability to eliminate insoluble crystalloids in solution in the urine. It is pictured that the urinary colloids carry on their surfaces insoluble urinary crystalloids by what is termed "adsorption." The normal daily amount of the colloid is sufficient for the elimination of the normal daily amount of the insoluble crystalloids. That these urinary salts are present in a supersaturated state in the urine is an important fact, both as regards the function of the colloids and as bearing on the precipitation of the salts in stone formation. For, if one disturbs this so-called colloidal balance by either increasing the crystalloids or decreasing the colloid surface area, there then occurs a precipitation of the crystalloids and their appearance in the urine as actual insoluble material.

Stripped to this simple viewpoint, again let me call to your attention the interrelation of this etiological theory with the three previous ones. For, first of all, infection with its morbid products, and epithelial degeneration, as from the vitamin A deficient diet, are both recognized as reasons for disturbance of the normal colloid mass; and wherever there is an increase in crystalloids, such as occurs in decalcification of the bony skeleton or in faulty bowel elimination, we see the opposite picture of an attempt being made to eliminate more crystalloids than there is assumed to be colloidal surface to hold them in solution. Therefore,

these four theories of stone formation, although each may not be constant or sufficient, are nevertheless closely interrelated

5 Our fitth theory is the recent one, where it has been pointed out that disease of a hyperplastic character in the parathyroids is responsible for decalcification of the bony skeleton and the occurrence of an actual calcium diabetes in the urine. As a result of the studies made at the Massachusetts General Hospital, it is claimed that this factor is present in ten per cent of all cases of renal calculus. Here we are unquestionably getting beyond the urinary tract and finding a causal factor of utmost miportance But when we concentrate our view upon the urmary tract, such hypercalcinum is not of itself a factor that produces a stone It works in well with the theory of colloidal imbalance, for here again we picture an excess of crystalloids over and above the surface holding power of the colloids, and as such, this theory of a reason for stone works in with the four previous ones as an interesting factor but not as an actual causal condition

There seems to be quite a gap between the theoretical mechanism of possible stone formation and our knowledge of its actual causation. I can see reason in these various theories on the etiology of stone that can be of importance as to how a stone may grow, but none of them, to my mind, give a satisfactory reason as to why a stone does occur, where it starts, how it actually originates, and why it is not washed away when still microscopic In the first place it is not unusual to watch a patient with a chronic phosphaturia, a chronic oxaluria or, probably most interesting of all, a chronic cystinuria, in whom, in spite of the persistency of this perversion of the normal, a stone does not form Secondly, we must realize that when a stone does occur in the renal pelvis, it virtually always starts as a umlateral lesion As no one of these theories is infallible in the production of stone, so also the control of no one of them is of unfailing virtue in the prevention of the recurrence of stone It is thoughts such as these which make me feel that these five theories, concerned with the etiology of stone, are all essentially secondary reasons, and none of them can be classed as a primary cause of stone formation Nevertheless, they are of the utmost importance, even as secondary reasons, when one takes up the

subject of the prevention of recurrence, for as such, each one has to be removed from the picture, or it remains as a potential invitation to the growth of a recurrent stone

The difficult part of this problem is to fit into these etiological factors the known variation in the actual chemical character of the stone itself. Such concretions are known to be formed from calcium oxalate. calcium magnesium phosphate, calcium carbonate, and calcium magnesium ammonum phosphate Again, sodium urate, ammonium urate, uric acid, and the rarer salts of eystine and vanthine are found It is easy to see that a disturbance in the calcium metabolism can very readily be a factor in the formation of a calcium stone, but there it must end, and certainly could have no relationship to the formation of a stone of uric acid, a urate or one of the rarer salts

It has been the existence of this multiplicity of theories, with the known divergence of stone chemistry, that has made it difficult for anyone to grasp or formulate a theory for stone formation, and this difficulty. I am sure, has been a reason why surgery has adopted the unfortunate middle ground of speaking of stone disease as an entity and, by so doing, losing all sight of etiology. Such a point of view has, of necessity, made it impractical to adopt any steps toward stone prevention and has led to the regrettable surgical attitude of removing a stone with a clean conscience, and with the feeling that the entire surgical lesion has been corrected

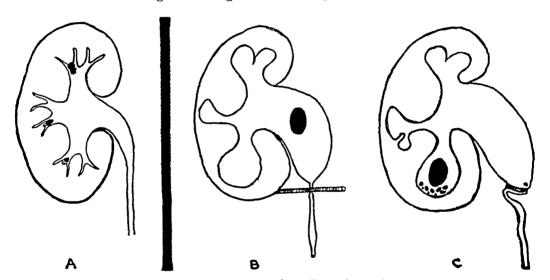

For the past few years I have attempted to explain the inconsistencies in the formation of a renal calculus by trying to separate the picture according to the chemical composition of a stone. This is to say that one would make a separate chapter according to the chemistry of a stone, and then try to write into that chapter a causal factor and perhaps elaborate further on diagnosis, treatment, and prevention In some of our pictures this has not been difficult to do The stone which follows a vitamin A deficiency has been shown to be consistently formed of calcium-magnesium phosphate. The stones which follow hyperparathyroidism have likewise been of a definite chemical char acter, and always a calcium salt

those stones which form in the presence of an infection, which produces an alkaline urine, have been consistently a triple

phosphate deposit.

But, there has been one very definite stumbling block which this mode of approach has not explained, and that is the occurrence of a laminated stone, in which might be a core of uric acid, a second lamination of urates, a third layer of pure oxalate crystals, and even a fourth deposit of calcium-magnesium phosphate. The failure to explain this phenomena has caused me to set aside the pure chemical theorization and to approach the story of stone from a new angle of thought.

renal colic due to a calculus measuring up to a centimeter in size, which has suddenly entered the upper ureter and has obstructed the same. X-ray reveals a shadow, just opposite the lower pole of the kidney. Urography proves this to be a calculus lying in the ureter, and behind it a pelvis that is beginning to show the evidences of primary back pressure. The stone has interesting peculiarities, both on the plate, and on examination after its removal. On the plate it is frequently heart (or arrowhead) shaped or else a long oval, and on examination it is of pure crystalline character, and of a single salt deposit. The arrowhead-shaped stone

A depicts three stages in the growth of a "primary" renal calculus. B and C illustrates the "secondary" renal calculus where obstruction plays the leading role.

Let me present this thought in very brief form. I believe there are but two basic causal factors which are capable of making a stone grow in a renal pelvis. The difference between these two possibilities can be sharply delineated, and the resultant stone shall be termed a "primary" or a "secondary" renal calculus, dependent upon the causal factor at work. (See illustration.)

In the first class or "primary" renal calculi, one finds those cases in which the clinical picture is especially clear, and every physician has experienced such a case in his practice. To it belongs the individual in otherwise perfect health, who is suddenly seized with the clinical state known as calculus colic. Examination finds a man in the throes of a primary

is generally smooth of surface, with a rounded point; while the ovoid stone has a highly crystalline surface, with one end evenly developed and showing sharp crystal points. But, the opposite end of each variety shows every evidence of having been the point of mural attachment, and one can see the cup-like depression which was unquestionably the site of fixation to the pelvic wall.

As I say, this clinical picture is unquestionably familiar to everyone, and one stops to ask these questions:—What caused that stone? How long has it been in existence? Where has it been? And why has it suddenly produced this severe clinical picture?

An answer to these questions I believe to be not difficult of formulation. It is my firm conviction that such a calculus has arisen as a gradual crystallization upon a lesion in the renal pelvis. Somewhere in the renal pelvis, most probably on a papilla, there has occurred a primary ulcerative lesion. It is of small size but with a raw surface, and thereon has occurred, through one of the above theoretical reasons, the precipitation and coalescence of urmary salts. Following the colloidal chemical theory, the salts so precipitated are probably those which, at that time, are supersaturated in the urine As such the deposit starts, and once started, has every reason to gradually merease in size Being so fixed, it gives no symptoms of its presence until, due to some factor, he it trauma, size, weight or sudden motion, it ceases to be a fixed concretion and breaks loose from its point of origin. The next natural course is nature's effort to extrude the calculus. and such extrusion means passage down the ureteral line of dramage, with the result that one sees the patient in his primary ureteral stone colic

A stone of this type is most chiracter istic in its configuration and, time and again, presents itself as a heart shiped concretion, from which one can almost picture that during its period of growth it crystallized about a basic papillary ulceration until, as above mentioned, its size allowed of its being no longer adherent Under such conditions it would be a fore gone conclusion that, when that time arrived, such a stone would break loose, become a freely movable body, and within the space of a few hours, pass from pelvis into ureter and produce the clinical symp-

tom of a Dietl's crisis

One thing remains to be explained, and that is the primary lesion. Here it is my feeling that primary papillary ulceration is of much more frequent occurrence than we have been led to suppose, or even made to think Such ulceration could be either infectious or trophic. In the past our pathologists have routinely examined kidneys at postmortem by opening them from the convex surface in toward the lulus As you well know, it is infrequent that the pulvis is thus competently opened or, if subsequently cut, is completely searched You cannot find in the textbooks on pathology of today any mention of any pathologic condition occurring in the renal pelvis, other than the generalized one of pyelitis or the very self-evident one of tumor The finer pathology of the renal pelvis has yet to be written I would like to emphasize the brilliant work in this respect recently published by Lieberthall and Von Huth, in regard to the prelitic lesions in renal tubercu-This demonstrated fact in renal tuberculosis is pregnant with possibilities in regard to the more frequent occurrence of papillary ulceration in other infectious states. The heart-shaped shadow so characteristic, and so frequently seen in these primary stones, almost invites one to visualize their growth about the apex of a renal pipilla, and if you will take the trouble to examine closely, with a hand lens, one of the characteristic olive pitshaped stones, you will again observe one end typical of freedom, and the other highly suggestive of mural attachment Again, it is interesting to note that these stones are, as a rule, consistently formed of a single urmary salt

In the second class belong the calculwhich form in a renal pelvis in which urinary stasis is present because of some obstruction to the normal urine outflow Examination by urography reveals the presence of hydronephrosis, and the stone grows as a complication of such a static condition It has been the tendency to look at this picture in a reverse order, making the stone the cause of the hydronephrosis, rather than the resultant effect of a hydronephrotic pelvis Such stones are frequently found actually floating and freely movable in their habitat They are nearly always smooth and ovoid. sometimes multiple and faceted and frequently laminated, being composed of diversified urmary salts. To me this picture is so closely akin to the recognized condition as seen in vesical calculus that it should need no further exposition

As the first class, which form as crys tallizations upon papillary ulceration, are termed "primary" renal calculi, so the second class, postulated upon faulty pelvic dramage, are called "secondary" renal calculi. The actual origin of the secondary renal calculi demands nothing more for a nucleus than a cluster of desquamated cells, a bacterial clump or a tiny clot of blood. They are as easily assimilated into our clinical pabulum as the familiar research.

ical stone. On equally parallel lines runs the observed fact that when all the essential factors appear to be present for a stone's growth, it does not, of necessity, materialize.

It remains to be explained why those stones, which are now termed "secondary," are frequently found to be formed of varying chemical laminae. This occurrence should almost be expected rather than, of necessity, be explained. There is no doubt that, in such a supersaturated liquid as the urine, certain salts, at certain epochs, reach the threshold of their insolubility, and precipitate in pure form over a period of time. Under these conditions there will be periods when one type of salt will be more easily precipitated than others, and the laminations will correspond to exactly such periods. Likewise, it is to be recognized that the growth of such stones can and does vary according to the type of deposit then being made, and we are all cognizant of the slow growth of the uric acid and urate stones, as compared to the rapid growth of the earthy and triple phosphate stones.

The factor of supersaturation of a urinary salt becomes of greater consequence the more we dwell on these facts and, as such, lends greater weight to the role of colloidal chemistry.

As this presentation is essentially a clinical approach to a pathologic state, so let us make it work in the reverse order and from the pathologic state of renal calculus deduct clinical applications and guidance.

Preoperative Study

Although borderline cases are bound to occur, it is extremely easy to look at almost any case of well-studied renal stone and decide to which of these two categories it belongs.

Patients with "primary" calculi nearly all enter the clinic in ureteral colic. The one point to be decided is whether to operate immediately or to attempt cystoscopic manipulations. If the stone is in the upper ureter, I am distinctly in favor of prompt ureterolithotomy; if in the lower ureter, I prefer to exhaust instrumental manipulations first.

The "secondary" calculi are essentially intrapelvic, and only when a fragment, or a daughter stone, gets away and into

the ureter, does typical colic occur. Roentgenologic studies in this type show an associated hydronephrosis, which too often is surmised to be secondary to the stone and the blockage therefrom, when actually the reverse is true, and the stone is secondary to the hydronephrosis. With the exception of the reported successful attempts to dissolve such calculi, their cure is essentially surgical. Dependent, as they are, upon an existing hydronephrosis, the surgeon should be more interested in relieving this primary morbid state and saving a kidney than in the mere existence of a complicating calculus.

Operative Deductions

Of the "primary" stones the vast majority will be found as ureteral calculi, though some, of course, get no further than the true uretero-pelvic junction. If our deductions are acceptable, their actual origin depends upon extrarenal causes. For accentuation one is tempted to put them down as due to prerenal causes. The greater number are probably due to focal infections, others to trophic disturbances, some to faulty dietary regimen, and still others to metabolic disorders. Be the cause what it may, the surgical handling is lithotomy, with every care taken not to create thereby the added insult of scar-tissue changes that may develop into obstruction later.

The "secondary" calculi present the real surgical problem. Here the lithotomy is but a step in the proper surgical handling. Keeping ever before us the picture of bladder stone, let us approach each and every case of secondary renal calculus in exactly the same spirit, making the stone of secondary interest, as compared to the acute problem of correcting the primary hydronephrotic state. Here the cause is always intrarenal (intrapelvic), and it is beyond the scope of this paper to discuss the surgical possibilities. But, if correction is not definitely and satisfactorily obtained, let me advise the removal of the kidney, for recurrence is almost a certainty.

I have allowed myself a few closing remarks on the prevention of the recurrence of renal calculi. This phase of the subject has been before us throughout the entire presentation, for until cause is known, prevention is perforce a very uncertain thing. I am trying to study every case of "primary" renal stone as one would study an arthritic—search out focal infection, look for allergic reactions, think of dietary habits, and make the necessary laboratory studies for metabolic disorders. The persistent stone former is a perfect laboratory for active research in this subject. There is a pet theory among some that patients go through a stone-forming age and that, once beyond that age, they cease creating further stones. I would like to suggest that, in all probability, the intercurrent removal of an infected tooth, a bad gall bladder, or some other chronic focal infection has much more to do with the cessation of the stone-forming habit than the mere passage of years. Local pelvic infection must be obliterated by every active means at our disposal, but in addition, let me urge that the patient be studied as a whole, and with the intention of ruling out every possible prerenal factor that may play a part.

The final word on the prevention of the recurrence of "secondary" calculi was said when discussing the surgical handling, for nothing short of perfect drainage of the pelvis and sterilization of the same will give any assurance of success; and let me add that this is at times most diffi-

cult to attain.

MEDICAL ARIS BLDG.

CASE REPORT

ALTERNATING BILATERAL SPONTANEOUS PNEUMOTHORAX COMPLICATING BILATERAL ARTIFICIAL PNEUMOTHORAX

CHARLES E. HAMILTON, M.D., Brooklyn
Chief Attending Physician, Division of Tuberculosis, Kings County Hospital
and

EMIL ROTHSTEIN, M.D., Brooklyn Junior Attending Physician

In the treatment of pulmonary tuberculosis by the use of artificial pneumothorax, one of the complications most to be dreaded is spontaneous pneumothorax. The patient receiving simultaneous bilateral pneumothorax is exposed to this complication twice as frequently, at least, as the usual unilateral pneumothorax patient, and the dangers are even more than proportionately greater.

We are reporting the case of a patient who, while receiving simultaneous bilateral artificial pneumothorax, developed a spontaneous pneumothorax, first upon one side and then upon the other, and sur-

vived both of these accidents.

L. H., female, aged 20, of Irish extraction, was admitted to the tuberculosis division of the Kings County Hospital on July 29, 1934. Her complaints were moderate cough and expectoration, and moderate toxic symptoms (anorexia, weight loss, and lassitude). These symptoms dated back three years, at which time a diagnosis of pulmonary tuberculosis had been made, and since then the patient had been on a modified rest regimen. Her clinical course had shown various periods of remission and exacerbation.

She was a thin undernourished girl, with normal temperature, pulse and respiratory rate. The only significant findings were in the chest, where over each upper lobe anteriorly and posteriorly were present dullness, diminished breath sounds and many moist rales. There were numerous tubercle bacilli in the sputum.

The first x-ray, two days after admission, (Fig. 1) revealed an extensive tuberculosis. On the night the upper lobe showed several moderate sized cavities, rather thick-walled, with little inflammatory reaction, extending to the second rib anteriorly. In the midfield (the third anterior interspace) was a cavity three cm. in diameter, also marked by the absence of perifocal reaction. The upper fourth of the left lung was occupied by several cavities, the largest about four by five cm., with more recent caseation extending to the fourth rib anteriorly.

Because of the extent of the pathology, it was felt that without some form of collapse therapy the prognosis would certainly be fatal, and therefore a plan of simultaneous bilateral pneumothorax was decided upon. According to the classification used in our Tuberculosis division the case was rated as Grade C—last resort case, in which the prograde is appropriate that it is the control of the control of the prograde in the control of the prograde is a section.

of successful collapse are very poor either because of the nature or the extent of the pathology, but in which there exists the possibility of salvaging an otherwise hopeless case by the use of collapse therapy.

Pneumothorax was started upon the left side August 4, the side of greater pathological activity. After a beginning selective collapse of the upper lobe had been obtained with seven refills, averaging 350 c.c. each, the right side was started August 23. During the next ten days an early selective collapse of the right upper lobe was obtained (Fig. 2) in spite of several adhesions. On

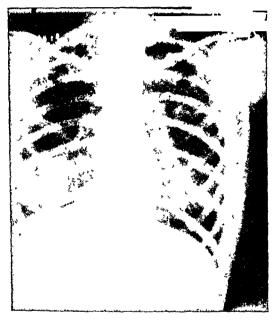

Fig. 1. Film on entry to hospital. Bilateral fibrocavitary tuberculosis affecting chiefly the upper lobes. Large cavity in the center of the right lower lung field

September 4 about one hour after a refill on the right side of 500 c.c., final pressure -6,0, the patient complained of severe right chest pain, marked dyspnea, and cough. Examination revealed extreme dyspnea, cyanosis, the heart far to the left, and slight subcutaneous emphysema of the right chest wall. Spontaneous pneumothorax diagnosed and deflation was performed on the right, the patient already being semicomatose. The intrapleural pressure was plus 10 cm H₂O Four deflations were performed within the next thirty-six hours, with a total removal of 2000 cc. of air. Marked subcutaneous emphysema developed, as far as the midabdomen, face, left chest, and right wrist. However, all symptoms gradually subsided within the next few days. There was no fever or pleural effusion. The x-ray taken a few days later (Fig. 3)

revealed an almost complete collapse of the right lung, with displacement of the heart and mediastinum to the left. The site of pulmonary rupture could not be visualized but it was apparently not through any of the major adhesions or cavities.

After a period of seventeen days, during which the right lung was allowed to expand partially, pneumothorax was again started, refills being given alternately at three day intervals. On September 28 about four hours after a refill on the left of 200 c c., final pressure 0.2 she complained of severe pain in the left chest, and of dyspnea. Ex-

Fig 2 Film showing an early bilateral selective collapse. There are air collections over each upper lobe Complete collapse is prevented by adhesions.

amination revealed cyanosis, dyspnea, and mediastinal displacement to the right. Deflation was performed on the left, the pressure being 8 cm. Six deflations were performed in a period of three days with a total removal of 2700 c.c. Fever developed to 103° F. but gradually subsided within the next ten days. time went on a non-toxic tuberculous empyema developed on this side. X-ray taken spontaneous after the second pneumothorax revealed (Fig. 4) an almost complete collapse of the left lower lobe, the upper being held out by a number of adhesions. The site of rupture could not be definitely identified, but it was not through one of the major adhesions or cavities. The patient's general condition improved and pneumothorax was again started on October 23. At the present writing she is receiving alternate refills on alternate sides at weekly intervals, apparently none the worse for her two harrowing experiences. In spite of adhesions to both upper lobes there is a selective collapse of each upper lobe and closure of the large cavity in the right lower lobe. Although the prognosis is still dubious the patient's chances for recovery are far greater than before the institution of treatment.

Discussion

The use of bilateral simultaneous pneumothorax in properly selected cases is

Fig 3 Film taken after the first spottaneous collapse. There is almost complete collapse of the right lung. The heart and mediastinal structures are displaced to the left, Subcutaneous emplysema of the right chest wall

now sufficiently widespread to require no further comment Spontaneous pneumothorax is one of the most dreaded complications of pneumothorax therapy, even in unilateral cases It presents the danger of immediate exitus from shock or asphyxia, the danger of persistent high-tension pneumothorax as the result of a valvular bronchopleural fistula, and often the development οf a mixed infection empyema with its usually lethal outcome When two lungs are being simultaneously collapsed the danger is immediately doubled. Other factors are also present, making the likelihood of a spontaneous rupture greater than in the unilateral case Some of these are: (1) the need of securing a selective collapse means that as a rule the lower lobes remain expanded, presenting the possibility of direct needle puncture of the lung at each refill; (2) since the bilateral case is usually more advanced than the ordinary undateral one, certain pathological features are more frequent (adhesions, emphysematous blebs, sub-pleural caseous foci), and it is these features that lead to spontaneous pneumothorax; (3) the possibility of an immediate fatal result from asphyxia is

Fig. 4. Film taken after the second spontaneous pneumothorax. Almost complete collapse of the left lower lobe. The upper lobe is held out by adhesions. The heart is displaced to the right.

markedly increased by the already impaired vital capacity,

We feel that in last resort cases with bilateral cavitation of appreciable size there are a number who can be saved by bilateral pneumothorax who would otherwise die. Our experience with bilateral pneumothorax leads us to believe that it is a type of procedure requiring great care as regards amounts of air, pressures, sites of needle puncture, etc. Frequent x-rays or fluoroscopes are imperative. Great patience is needed in the presence of adhesions, for it is especially in attempts to stretch these that accidents will occur.

1189 DEAN STREET 847 LINCOLN PLACE

THE DIAGNOSTIC SIGNIFICANCE OF GALLOP RHYTHM

C. S. DANZER, M.D., F.A.C.P., Brooklyn

For a long time, I have been struggling with the problem of gallop rhythm. must confess however, that I have been only partially successful in removing the haze from my eyes. I wondered whether it were better to defer publication until greater experience and deeper reflection yielded more light, but on the other hand, withholding thoughts too long subjects them to staling influences, a fact that should not be lost sight of. Hence, the decision to write my present views on the subject of gallop rhythm in the hope that others similarly engaged but better endowed intellectually or having greater clinical or research facilities, may elaborate on my meager contribution, thereby vielding more, in a limited period, than I could, working alone.

Because the subject is complicated hardly justifies one in holding with Bouillaud¹ that it is a *signe de luxe* or in dismissing it with the indifference and resignation of many text writers of the

past and present generations.

Some confusion has arisen because of the emphasis placed on the timing of the extra heart sound in gallop rhythm, and the reference to the presystolic, protodiastolic or mesodiastolic character of gallop rhythm, is frequently met with, in the literature. Practically, we need not go into this matter any more than to say that there are some cases in which the accessory sound is fixed within the cardiac cycle, and others in which its time relationship varies (e. g., when the presystolic becomes a mesodiastolic gallop); the latter resulting from the impairment of conduction from the auricle to the ventricle or from a shortening of the diastole incident to an increased heart rate.

It is essential at the outset to separate true gallop rhythm from the reduplication and splitting of the heart sounds; the latter often mimic the former, but their clinical significance is very different. There are, however, exceptional instances when it is impossible to tell whether a serious gallop rhythm or a harmless split

first heart sound is heard; this fortunately is not the rule. Further observation and repeated auscultation solve the difficulty.

Bouillaud who first heard it called it "bruit de rappel" and Traube described its thumping character, christening it with the name "Gallop Rhythm."²

To those with a flare for instrumental methods, it might appear futile or meddle-some to attempt such clinical studies with the unaided sense of hearing, or that this problem might more profitably be pursued by means of heart sound records. But the fact that the human ear is capable of estimating sound differences of .008 of a second, will emphasize the refinement of the instrument that our Creator has given us, and I hope to show, that uncomplicated bed-side observations made with the ear, if properly interpreted may not be entirely devoid of merit.

What is gallop rhythm? It is a tripling of the heart sounds due to the addition of an extra sound which comes just before the first sound; the intervals between the accessory, the first and second sounds are about equal. The three sounds may for convenience be described as occurring in three-quarter ("waltz") time. This characterization may differentiate it from the other accessory sounds, in which the extra sound is coupled more closely with the first or second heart sound, resulting in an inequality of the pauses between the

accessory and the normal sounds.

The extra sound in gallop rhythm is now definitely assigned to the vigorous and audible contractions of the auricles. This hypothesis was originally advanced by Charcelay³ (1838) and later independently by George Johnson⁴ (1876), and was confirmed by the graphic studies of the heart sounds by D. Gerhardt,⁵ and more recently by Mond and Enid Oppenheimer.⁶ These workers have shown that the extra sound is presystolic in time and simultaneous with the P (auricular) wave of the electrocardiogram. I am satisfied with the doctrine of the auricular origin of these extra sounds because I have seen

gallop rhythm disappear when auricular fibrillation supervened, and reappear when the fibrillation stopped. In fibrillary arrhythmia, it is common knowledge that the auricles cease to contract, but quiver instead. Since the extra sound occurs only when the auricles contract forcibly, it is obvious that the quivering of these thinwalled chambers is hardly enough to create audible sounds.

Gallop rhythm is more clearly discerned in hypertension where the thumping or pushing quality of the auricular sound is felt by the palpating finger and its dull, low-pitched sound perceived by the ear. Palpation is often more conclusive than auscultation. Firm pressure with the stethoscope generally obliterates it and the best way to listen for auricular sounds (c. g., in gallop rhythm or heart block) is by applying light pressure with the stethoscope. I am indebted to Prof. Arthur D. Hirschfelder of Minnesota for this practical hint.

To re-emphasize: The accessory sound in gallap rhythm is presystolic in time and due to a vigorously contracting auricle. Its significance will now be explained.

Physiology of Auricular Contraction: Under normal conditions, the auricular contractions are unessential to the diastolic filling of the ventricles. When there is an increased resistance in the ventricles or the A-V valves, the auricular contractions become significant. The commonest example of such valvular constriction is mitral stenosis where the hypertrophied left auricle helps to drive the blood through the narrowed mitral orifice thereby reducing the imperfect filling of the left ventricle. In the earlier stages of the heart failure of mitral stenosis, it is the atrophy of the left ventricle rather than the insufficiency of the right ventricle and lesser circulation which is of primary importance.

Another illustration of the importance of vigorous auricular contractions is in heart failure. Here the residual blood in the ventricles increases and the auricles contract powerfully in order to drive the blood into the partly-filled ventricles during diastole; the resulting increase in intraventricular tension causes a greater distension of the ventricles—the muscle fibers of the heart become stretched and this results in a more complete evacuation

of the ventricles during the ensuing systole (Starling's Law).

11

Hence, an early indication of the ventricular failure is, forcible auricular contractions, which may under certain conditions give rise to audible sounds characteristic of gallop rhythm. The phenomenon may be concurrent with cardiac decompensation and fugacious, or it may be permanent and indicate a persistent suboptimal (insufficient) cardiac condition. Concerning the symptoms and treatment of the milder forms of visceral insufficiency, I refer to the splendid work of Januschke, details of which cannot be

presented in this paper. The time of the audible auricular contraction in the gallop rhythm of heart failure, depends on the degree of decompensation. The more severe the latter, the earlier in diastole—when it approaches With mesodiastolic phase. restoration of compensation, the auricular sound moves nearer to the first (ventricular) sound, so that it becomes presystolic and later comes so close to the first sound as to give rise to a split sound, which is finally replaced by the normal, single heart-sound.

Gallop rhythm is probably the most direct sign of heart failure and ferhaps of myocardial disease especially when this phenomenon is associated with an increase in the P-R interval or an inversion of the T waives in the first two leads of the electrocardiogram. This symptomatic duet may be regarded as a "reaction of degeneration" of the myocardium.

Gallop rhythm occurs most commonly in the heart failure of essential hypertension, chronic hypertensive nephritis and coronary thromhosis. In the last condition, it usually appears several days or more after the onset. In hypertension, especially when the diastolic pressure is concurrently elevated, gallop rhythm should be diligently sought for because its detection may yield significant prognostic and therapeutic leads. Such cases should be ausculated both after exercise and while the patient lies on the left side.

The infectious diseases in which gallop rhythm may indicate myocardial degeneration are diphtheria and pneumonia. Its presence is an ominous sign and the patient should be watched with extreme care and unnecessary movement (espectation).

cially in diphtheria) carefully avoided. Sudden death on sitting up during the convalescent period of diphtheria, may be due to unsuspected myocardial degeneration which might have revealed itself by a gallop rhythm which was overlooked. Such patients should be kept in bed at least as long as the gallop rhythm persists. Digitalis, if given at all, should be administered in small or moderate doses; large doses may do more harm than good.

In coronary thrombosis, it is an important prognostic sign, and the proximity of the accessory auricular to the first ventricular sound bears some re-- lationship to the severity of the disease: the nearer it is to the first sound, the less the involvement, and vice versa. There are, however, rapidly fatal cases without gallop rhythm. Gallop rhythm may outlast the other clinical signs of acute heart failure but as long as it exists, compensation can hardly be considered restored, and dyspnea on effort or emotion, nocturnal attacks of cardiac asthma (with or without edema of the lungs) are almost the rule; subsequent attacks of coronary closure are quite common.

Gallop rhythm generally occurs as a sign of serious myocardial disease with impending or obvious heart failure. It also occurs occasionally in: (1) compensated, aortic insufficiency, (2) severe tachycardia, (3) Graves' disease, and (4) auricular extrasystoles, without concur-

rent heart failure.

Aortic insufficiency with good compensation may be associated with gallop rhythm due to a forcibly contracting left auricle and I presume the mechanism is the same as the one advocated by Austin Flint to explain the functional presystolic mitral murmur in aortic regurgitation: the eventration of the mitral leaflets by the gush of blood into the left ventricle during diastole thus forcing the left auricle to contract against a resistance and create audible sound vibrations.

In Graves' disease, gallop rhythm is occasionally heard. It may be due to exaggerated auricular activity resulting from neurocardiac stimulation. There may be in addition a supervention of cardiac insufficiency which might exaggerate this phenomenon. In the tachycardias (including auricular flutter and other types of paroxysmal tachycardia) vigorously

contracting auricles may induce gallop rhythm. Here, too, the associated heart failure incident to the tachycardia may be a significant factor. When the normal heart rate is established, both gallop rhythm and other signs of heart failure, disappear.

A diagnostic point worthy of emphasis is that auricular extra-systoles may disclose their origin, by the addition of the audible presystolic element which accompanies the premature, but not the normal beats. Obviously a "galloping extra systole" does not indicate heart failure. In a recent case of mine the P wave of the premature contraction was mounted on the T wave of the previous beat, showing that the auricle contracted while the ventricle was still in systole. The impediment to the blood flow from the auricle caused the latter to contract forcibly and produce the accessory sound.

There is an apparent relation between constitution and gallop rhythm, in that the latter is most commonly heard in broad-chested persons, while the physiological reduplications and split sounds are more frequent in long, thin people.

Physiological Splitting and Reduplication: First Heart Sound. It is essential to review these briefly in order to distinguish them from the gallop rhythm described above. R. Geigel, Jagic, and Pillsbury have emphasized the frequency of split first sound in normal hearts. They are generally heard best in the third left interspace between the sternum and mamillary line.

The first sound consists of two elements: (1) Muscular element due to the contraction of the ventricles; (2) vascular element resulting from the impact of the columns of blood thrust against the walls of the aorta and pulmonary artery. The first (muscular) element is low-pitched and dull, the second (aortic) element is high-pitched, clear and short. The accentuation is generally on the first element.

We may dismiss the theory of "asynchronism of the ventricles" as an explanation for the splitting of the first heart sounds, as one lacking in proof. This false notion has unfortunately become anchored in current textbooks.

Under pathological conditions (e. g., essential hypertension or chronic hyper-

GALIOP RHYTHM

tensive nephritis) the interval between these two elements is lengthened and the split sound may assume the character of a reduplication the latter represents the shadowland between the physiological and pathological

A split first sound while generally physiological is otherwise if accompanied by a prolonged P-R interval or an in verted T wave on the electrocardiogram It then indicates myocardial degener-

Reduplication of the first sound textbook statements to the contrary, does not occur in mitral stenosis Reasonable confusion may exist when the presystolic murmur is very short (rudimentary), it may then be taken for the presystolic

element of gallop rhythm

Second Heart Sound A physiological splitting of the second sound at the base of the heart is heard best during inspiration and is due to the premature closure of the pulmonary valve resulting from the predominant influence of the negative intrathoracic pressure on the pulmonary artery rather than on the north asynchronism of the closure of the semilunar valves accounts for the splitting of the second sound The first element, which is caused by the closure of the pulmonary valve, is dull and low-pitched. the second element arises from the aortic valve, is clear and high-pitched pathological splitting of the second sound with accentuation of the closing sound of the pulmonary valves obviously occurs in pulmonary arterial hypertension incident to mitral valvular disease or leftsided heart failure

A familiarity with the acoustics of the second heart sound is important in ex planning the absence of an accentuated A-second sound in hypertension . Often it is not heard over the conventional aortic area but to the left, where it is mistaken for the second pulmonic sound reason for the confusion lies in the overlapping of the areas over which these respective sounds are projected aortic zone has the shape of an horizontal oval extending from the second interspace to the right of the sternum to a corres ponding point on the left side, the pulmonic zone is a vertical band a little outside of the left aortic zone in the second and third left interspaces. In the left second interspace, both aortic and pulmonary sounds intermingle In case of doubt concerning the interpretation of the second sound to the left of the sternum, the latter should be compared with that heard over the conventional aortic area

A diastolic reduplication of the second sound at the apex is often heard in mitral stenosis where it is of diagnostic value The explanation of its mechanism given by the French school, is a chek due to the unfolding of the rigid, stenotic, mitral valve segments during diastole ("Claquement d'ouverture nutrale") In some instances of mitral obstruction, there may be in addition to the reduplication of the second sound at the apex, a splitting of the second sound at the base mechanisms and the acoustics of both sounds are different. The latter is higher pitched and is separated by a shorter interval than the former. The cause of one is the high pressure in the pulmonary artery, that of the other, the unyielding mitral valve

While the physiological splitting of the second sound is best heard during inspiration, true gallop thythm is heard best at the end of expiration when the heart is denuded (not covered by the lungs)

A physiological third heart sound (Gibson, Thryeri') is occasionally heard in young thin chested people especially boys It is heard best with the subject in the horizontal position and slightly rotated to the left and is heard and felt as a soft postdiastolic shock against the listener's eardrum This is not to be confused with the middiastolic third sound which though rare, occurs in "adherent pericardium" and is due to the diastolic thrust of the apex in consequence of the antecedent systolic retraction

Diagnostic Technic for Eliciting Audible Auricular Contractions

The first rule is to ausculate early in the course of the examination while the patient is still excited. If the patient has become composed and a gallop rhythm is suspected and not clearly made out, he should be exercised moderately and the gallop rhythm may appear The cardiac apex should be felt and then ausculated in the left lateral position The finger should be placed against the cardiac apex near the stethoscope, or the thumb placed on the external carotid artery while listening to the heart. This will facilitate the timing of the extra sound. In true gallop rhythm, the accent is generally on the second or third element, not on the first (auricular) element. The stethoscope should be pressed against the chest lightly and those familiar with the wooden monaural stethoscope, used abroad, will find it quite useful for this purpose, for while the head rests on the earpiece of the stethoscope it is capable of feeling the impact of the heart beat transmitted along the stethoscope thereby permitting simultaneous palpation and auscultation.

14

Treatment

The therapeutic measures that should follow the discovery of gallop rhythm are as follows: The blood volume should be reduced by moderate venipunctures (150-200 c.c.) at irregular intervals of days, weeks or months depending on the severity of the case. Venostasis or the application of four blood pressure cuffs on the four extremities, a method that I have described on previous occasions, by means of which the veins and not the arteries are compressed, will be found very useful.

Dehydration by means of the injectable. mercurial-diuretics is valuable. Digitalization in moderate doses (never massive) should be employed. The fluid should be restricted to one liter a day and salt should be reduced or replaced by one of the salt substitutes on the drug market.

If gallop rhythm is heard during an attack of coronary thrombosis, where it is such a useful diagnostic measure, it should be followed with care. Patients must not be allowed to get out of bed for some weeks after its disappearance. Its reappearance when the patient is out of bed demands his prompt return to bed.

Patients in whom gallop rhythm is heard, who complain of dyspepsia, may derive benefit from a periodic rest-in-bed for at least one day a week and such patients may get symptomatic relief from the routine use of ten grains of diuretin peppermint water dram of taken at bedtime or during the spell of "indigestion." 216 CLINTON AVENUE

FIRST INTERNATIONAL CONFERENCE ON FEVER THERAPY

The first international meeting on fever therapy will be held in New York City, September, 1936. The use of fever induced by physical and other agencies as a therapeutic procedure has received universal attention in the past few years. The conference will aim to collect and crystallize available data in this field. Therapeutic, physiological and pathological phases of fever will be discussed.

The suggestion for this conference originated with a group of interested European physicians. Five national conferences have already been held in the United States.

It is planned to translate abstracts of all the papers into French, English, and German. In order to make the printed copies of the transactions available for the conference, it is necessary that manuscripts and abstracts be sent in not later than June 1, 1936. Those interested in participating are requested to make early application.

Further information may be had from the Secretary, Dr. William Bierman, 471 Park Avenue, New York City.

The San Francisco County Medical Society is broadcasting a program every Tuesday evening called "Science Edits the News," to give the public facts in an ethical manner about newspaper items related to health and medicine.

TREATMENT OF UNDESCENDED TESTES BY THE ANTERIOR PITUITARY-LIKE PRINCIPLE FROM THE URINE OF PREGNANCY

ALLA GOLDMAN, M.D., ABNER STIRN, M.D. and JOSIPH LAPIN, M.D., New York City

Since our original paper¹ on this subject we have studied additional cases. The procedure used was as follows.

1 Bodily measurements were taken of all important points, and compared with Englebach's standards before and after treatment

2 Prolan A and ovarian hormone tests were done on the urine of each boy before treatment in order to find what relationship these may have on the conditions found

3 Photographs were taken before and

after treatment

4 X-ray of the sella turcica, glucose tolerance, and basal metabolism tests were done where indicated to rule out

other endocrinologic defects

5 The position and size of the testes were carefully evaluated by at least three physicians on the initial examinations. Where a testicle entired the scrotum after a hot bath, or on downward mas sage over the inguinal canal, such case was not admitted to treatment.

The difficulties inherent in a proper evaluation of cases suitable for treatment become apparent in a review of the literature on the frequency of undescended testes Thus Drake' in a recent report gives a figure of one half of one per cent while other investigators run as high as five per cent. No statistical analysis in the literature differentiates the position of the testes, 1e, abdominal, high or low in the carril, or high in the scrotum Obviously such wide discrepancies must be due to differing methods of examination and evaluation of what the term "undescended" really should be applied to For the sake of rigidity of standards we have admitted to this study only those testicles definitely abdominal or in the canal, which cannot be expressed into the scrotum

The position of the testicle is the important factor in its function "Since Groffith's work in 1893, many researches have demonstrated that the degeneration of undescended testicles is due to their removal from the scrotal influences, which acts as a theimoregulator, producing the cooler environment required by the testicle for its germ-cell producing function. Abdominal testicles become functionally useless; those having a low inguinal canal position or an upper serotal one may occasionally contain some spermatozon. (Allen) The distance of the testes from the low serotal position is then a determining factor in its function.

Etiology

Counseller finds that the method by which the testis gets through the abdominal wall to the scrotum is not clearly understood but its success or failure is often attributed to the gubernaculum Supporting this theory is the fact that the gubernaculum not only atrophies following descent of the testis, but if the testis is either undescended or ectopic, the gubernaculum is either absent or deficient in its lower attachment.

Certain observers feel that the guber medium acts as a tractor and pulls the testis into the scrotum, others believe that it merely acts as a guide directing the testis into its normal position

Burdeck and Coley blist the following conditions which may be regarded as

causing arrest of the testicle

A Within the Abdomen (1) Mesorchum too long, so testicle hangs too freely, and it is prevented from engaging in the opening of the processus vaginalis (2) Adhesions between mesorchium and adjacent portions of serous membrane, the result of an intra uterine fetal peri (3) Lack of action of the internal fibers of the cremaster (4) Spermatic vessels may be too short (5)Certain forms of hermaphroditism (6) Fusion of testicles

B Within the Inguinal Canal (1) Lack of development of the inguinal canal, external ring, or one half of scrotum (2) Deficiency or absence of lower at-

tachments of the gubernaculum, or diminished activity of its muscular fibers. (3) Retraction by the action of the cremaster after the testicle has gained its normal position in the scrotum. (4) Pressure of a truss for an accompanying hernia.

None of the literature discusses the mass of the testis as a factor in non-descent, but a study of the mechanics would seem to indicate that an increase in the mass of the testicle would be an important factor in its descent.

Effects of the Anterior Pituitary-like Prolan Principle of the Testis

This increase in the mass of the testicle can be secured by the injection of anterior pituitary-like hormone (prolan) from pregnancy urine. Engle⁶ says that from the data acquired through the study of a series of animals, both rats and monkeys, the following conclusions may be drawn: (a) The testis weight of animals treated with pregnancy urine is considerably increased, and (b) the interstitial mass hypertrophies greatly. Working with seven monkeys, he⁷ found an increase in testis size, due to an increased tubule growth, and to an increase in the interstitial cell mass; and later⁸ he found the weight of the testis approximately doubled and the scrotum increasing in size and turgescence. He felt that with the external os open and the gubernaculum pulling down, an increase in the weight of the testis would produce descent.

Smith and Leonard, working on normal rats, reported similar results even from prolonged injections, though some investigators had reported subsequent involution of the interstitial cell mass, and a decrease in the size of the testis. This occurs only in hyphophysectomized animals.

Robson and Taylor¹⁰ found that injections of pregnancy urine in immature male rats showed marked effects on the development of the testes and on the whole genital system, the seminal vesicles becoming enormously enlarged, and the penis larger and longer, but there was no effect on spermatogenesis.

Aberle and Jenkins¹¹ report similar results in a group of five monkeys, the hormone causing complete descent in one animal and partial descent in four. In

these four animals, the fascia surrounding the vas deferens and spermatic vessels was too short to allow the testes to reach the lower part of the scrotum.

Plan of Treatment. Injections of the anterior pituitary-like principle of the urine of pregnancy (as prepared by Squibb & Co. under the commercial name of follutein). It contains a mixture of prolan A and B; A being the follicle-stimulating factor, and B the luteinizing factor. It is now standardized at 125 rat units to the cubic centimeter. Injections ranged from two to twenty-one a week, individual dosages from one c.c. (125 rat units) to three c.c. (375 rat units). (a) Ambulatory patients two to three injections a week. (b) Hospitalized, one to three injections a day.

No other medication was given in the

majority of cases.

Results. Eleven patients from 9 to 23 years of age, were under treatment for two to twelve months, and received a total from 1,800 to 14,000 rat units, and increase in the size of the testes and descene into the scrotum was attained in ten cases. Changes in bodily measurements to a more masculine type occured in five out of the seven considered Fröhlich types at the outset. Four cases had small external genitalia; in all four there was sufficient hypertrophy of the penis and increase in size and rugosity of the scrotum to be called normal when discharged.

These results compare favorably with those of other investigators. Thus Sexton12 was successful in producing descent of the testicles in four of six boys, and in producing growth of the external genitals in eleven out of thirteen boys with genital underdevelopment. The two failures to produce descent were in thin boys. Cohn,¹³ in four cases of nondescent, produced complete descent in three, and explains his failure in the fourth as due to mechanical obstruction. However, he reports ten injections of a total of only 1,000 rat units, a very much smaller dosage than we and others have found necessary.

Our one complete failure (Case 6) was a normal boy of twenty-three with normal sex development, but a left testicle completely abdominal. He has been under treatment only two months, with a

total dosage of only 1,800 rat units. For this reason more intensive treatment has been begun, although no result has been seen as yet

Rubmstein¹⁴ points out that since testicular descent is believed by some to occur as a passive phenomenon as the gland enlarges, and since the internal abdominating is normally closed in the human and incaque at birth, it is questionable whether descent would occur if the testes were intra abdominal prior to treatment. He treated a ten and one half-year-old Frohlich type with two abdominal testicles with drily injections for five months and secured descent of the testes, marked sex growth, and changes in bodily measurements.

We cannot as yet judge whether our fulure was due to insufficient dosage, inchinical obstruction, or to atrophy of the testes which had been abdominal after spermatogenesis occurred.

In three other cases which had one abdominal testicle (8, 10, and 11), treatment was partially successful, the testes entered the canal or the scrotum, there were marked growth of the external genitalia and changes in bodily measure ments.

Drake has shown the frequency of spontaneous descent, and the objection is often raised that descent would have spontaneously occurred in the time under treatment For this reason one case (7), eleven years old, with both testicles just pulpible high up in the canal was hospitalized and given 250 to 750 rat units three times a day The testes became markedly swollen and prinful within one week, the scrotum doubled in size child ran a temperature up to 103° F, with severe chills, and the leukocytes rose from 9 200 to 23,800. Dosage was then reduced, and the child remained in the hospital one month, receiving a total of 14,000 rat units At discharge both testes were large, the rudimentary, labialike scrotum had become large and rugose and the small penis had hypertrophied markedly

Aberle and Jenkins (10c cit) discontinued injections in one case because reaction was too severe. We have never found this necessary, as a reduction in the dosage seemed sufficient.

Comment

Age at which injections may be started is a controversial point. Cooperso found that undescended testes in boys over two and a half or three years of age showed a reduction in the number and size of the tubules and an increase in the intervening stroma For this reason Aberle and Jenkins11 treated a three year old boy successfully But Wangensteen16 in experimental work on unde seended testes in dogs showed definitely that if artificial cryptoichidism was produced before any spermatogenesis had occurred, none of the degenerative changes took place in the testis, however, if cryptorchidism was produced after spermatogenesis had begun, then de generative changes occurred in the testes Spermatogenesis is thought to occur as early as the unth year, although complete function rarely occurs before fourteen Therefore, Counseller' feels there is no urgent reason for treatment before

the muth year

Another reason why treatment was deferred was the possibility of premature sex function Engle¹⁷ feels that the dangers of precocious sex maturity in a child under mine are very real, and that the injection of large doses of a potent hormone into young children presents possibilities of real danger to the whole endocrine system. Case 8 one of twins, is interesting in this connection, as the twin treated for undescended testes has developed premature sex power, erections, and nocturnal emissions, which are lack-

ing in his normal brother

In view of this we have selected nine years as the earliest age at which we will start treatment. It seems desirable that we should not wait beyond thirteen years, when spermatogenesis brings atrophy to the undescended testis.

2 Frequency of injections seems a mat-

ter of choice

3 Size of dose No serious reaction occurred with any dose from 125 to 750 rat units, but as with Case 7, extremely large doses sometimes produced a painful swelling of the testicle. Our average dose is therefore 250 rat units

4 Possible dangers are illustrated by the precocious sex maturity in Case 8 Evansi⁸ found the testicles themselves actually decreased in weight and seemed

A PARAMETE

to be damaged by the injections of anterior pituitary-like hormone, but this was in work with rats. Collip and his coworkers,19 working with white rats, have demonstrated histologic changes in the descended testicles by injections of the anterior pituitary-like principle of the urine of pregnancy.

2. Increase in the size of the testes and descent into the scrotum was attained in

ovaries and hypophyses of white rats given continuous injections of hypophyseal extracts. The authors have found no specific references in literature describing definite damage to the human testis as a result of prolan.

Conclusions

1. Eleven boys were treated for un-

ten cases.

3. The one failure was in a boy of

twenty-three with a completely abdominal

left testicle. 4. Indications for treatment have been

discussed.

Acknowledgment

The authors wish to express thanks to

Dr. Joseph Felsen, the Director of Laboratories and Medical Research of the Bronx Hospital, and to Dr. Raphael

Kurzrok, for very valuable suggestions and laboratory assistance.

TO STUDY 100 DEMENTED BRAINS

The brains of more than one hundred men, women, and children who have died of dementia praecox will be materials for research through which two Albany psychiatrists will seek its cause and cure.

The research is being executed by Dr. Lloyd H. Ziegler, professor of neurology and psychiatry at the Albany Medical Col-lege, with the assistance of the graduate student resident in neurology and psychiatry,

Dr. Robert J. Stein.
The study has been made possible through a \$2,000 grant for one year's research, from the Research in Dementia Praecox Foundation established by the Supreme Council of the 33rd Degree, Northern Masonic Jurisdiction. A fund of \$40,000, available for the first year's study, has been divided among 10 cities throughout the United States. The work is under direction of the National Committee for Mental Hygiene.

The foundation was established after the Masonic order sought advice on the most important medical problem of the day with which they might assist.

"We will be pioneers," Dr. Ziegler said. "We will not deal with patients but with the brains of persons who have died from the disease. Our research will be conducted as a laboratory study in the college. It will take several years. We shall report periodically.

"Dementia praecox is a disease characterized by a lack of capacity of persons socially and occupationally to adapt them-selves to their environment," Dr. Ziegler pointed out. "When it is realized that more than fifty per cent of the beds in all America's hospitals are occupied by sufferers from this single malady, it can be understood how important economically it is to understand its causes,

"While medicine and surgery have made vast strides during the years, so far as anything of value is known regarding dementia praecox, we are still in the dark ages.'

Pupils at many schools now receive sunray treatment. They declare that it is much pleasanter to take than the old-fashioned method of tanning .- The Humorist, London.

PLASTIC RECONSTRUCTION OF NASAL DEFORMITIES

KEITH KAHN, M.D., New York City

Because the nose is the only unprotected organ in the face, its deformities are far more frequent than any other facial disfigurement. The rigid structure and fragile framework of the nose are particularly important factors in its deformation.

The shape and size of this organ are definite racial characteristics. However, hereditary syphilis and dysfunction of the endocrine system frequently result in nasal deformities.

As an organ the nose has the important functions of (1) Promoting the sense of smell; (2) facilitating normal breathing; (3) permitting proper drainage of the execretions of the nasal sinuses; and (4) contributing to establish normal facial balance. The present article has to do with the last of these; i.e., disturbed facial balance.

Normally, the nose occupies the middle third of the face and traverses a straight line through its center. Any deviation of the nose, therefore, comes within the scope of the treatment under discussion. Any individual whose nasal deformation prevents the performance of his daily duties and deters association with his fellow men with a feeling of physical normalcy, should be encouraged to avail himself of plastic surgery.

It is unfortunate that the majority of plastic operations are performed in private hospitals, since such hospitals are usually beyond the reach of those financially handicapped. Such persons will unfortunately put up with their afflictions and follow the pursuits open to them. And though a number of these patients will seek relief from, say, impaired breathing or similar symptoms in clinics especially suited for such purposes, most of them find no recourse to treatment which might correct the hideous facial disfigurement that keeps closed many lines of work to them and makes their social lives a burden.

Less than 10 per cent of all nasal corrections are undertaken for "beauty purposes"; more than 90 per cent of the clinical patients submit to such operations

because they are unable to secure suitable employment. Patients who come to the plastic surgeon with a deformed nose frequently present one or several of the following reasons for operation:

- (1) Neuroticism, such as self-consciousness, mental depression, inferiority complex (which in most cases is a result of the handicap), and other disturbances that might be considered of a neurotic origin or be a contributing factor to a psychoneurosis. Fully 80 per cent of all of these patients suffer from neurotic tendencies.
- (2) About 80 per cent of all patients suffer from impaired breathing. In most instances plastic operations will improve this condition. However, these operations do not in any way replace—nor are they intended to do so—more extensive submucous resection.
- (3) About 40 per cent of all patients seek the plastic surgeon because of social handicaps or because they are unable to find employment in their chosen field due to their deformity.
- (4) Strange as it may seem there are less than 10 per cent who seek the plastic surgeon for beautifying purposes.

It is well to remember that the plastic surgeon is concerned with the supporting framework and the mechanical arrangement of the anatomical structures of the nose rather than with its pathological conditions which should be taken care of by the rhinolarynologist. This article for that reason deals primarily with the proper realignment of the malformed and malposed nasal parts and the mental and physical benefits derived therefrom.

Nasal deformities may be hereditary or the result of trauma. Congenital malformations may be confined to the superficial structures, while traumatic deformities usually involve the deeper tissues of the nose. In the latter cases the reconstructive process naturally is more complicated.

As in most instances of surgery the patient's general condition should be known to the surgeon. Heart conditions, blood pressure, the coagulation time of the blood, and any active pathological

conditions in the nasopharity or the neighboring structures, which may interfere with the operation or its result, should be known. Another important factor is the healing ability of the patient. It is necessary that the extent of any previous inval operations be well established, and of course, that syphilis be eliminated by means of laboratory tests.

The 5 types of nasal deformaties are (1) Humped or hooked nose; (2) long nose, (3) crooked nose, (4) saddleback or flat nose, and (5) broad or fat nose. The occurrence of each depends on

habits and race

Because of the delicacy of plastic operations—on the nose as well as on any other part of the body—it is imperative that the operator learn how to model a nose from clay before attempting rhinoplastics, for it would be as unwise to attempt such an operation without clay modeling, as it would to attempt surgery without knowledge of anatomy

Preoperative Procedure

Preparation is the same regardless of the type of nasal deformity A combination of codeine and aspirin, administered orally one hour before operation, is excellent as a preoperative sedative. This does not produce the postoperative nausea and vomiting that so frequently follows the administration of morphine salts However, operators who are not accustomed to using local anesthesia will find morphine sulphate more effective In the author's experience, the barbiturates have proven unsatisfactory. There seems to be a great tendency to hemorrhage 4 to 12 hours after operation in cases where the drugs have been employed preoperatively If general anesthesia is used the customary combination of morphine and atropine by hypodermic injection is preferable

Humped or Hooked Nose

This is by far the most frequent type of deformity encountered Estimates vary between 50 and 75 per cent The incidence is highest in commercial centers where the Latin, Arabic (which is usually hereditary but may be traumatic in origin), and Hebraic races are numerous. The malformation is characteristic of these races, and the frequency de-

pends directly upon racial distribution It is overdevelopment of the supporting structures that distorts the nose both auteriorly and inferiorly

There is one type of patient upon whom the attention of the profession should be focused with serious intent, for it is usually his unsfortune to have one or two unnecessity operations. The patient is usually thin and underweight, nervous, and possesses a very long, thin, humped nose The nostrils are narrow and the cartilages of the alae are very thin and flexible. The chief complaint is difficulty in breathing Examination reveals congestion of mucous membranes, moderate degree of deviation of septum, and swelling of turbinites. The history establishes the fact that the patient is a mouth breather, suffers from frequent sore throats even though the tonsils have been removed, and expectorates large quantities of mucus on arising in the morning The first unsuccessful opera tion is usually a submucous resection, the second may be an attack upon the enlarged turbinates. Neither operation affords the patient any reliet. In these cases, which are not as infrequent as one would think, the external examination of the nose is most important can be seen to collapse on inspiration and adhere to the septum if the nasal secre tion is inclined to be sticky. The patency of the nasal orifices depends upon the support of the alac by the literal cartilages. If the cartilages are too thin and flexible to serve as a supporting frame work, the above described condition is the result, and its relief can be secured only through plastic reconstruction. This is mentioned below

Except in rare instances the operation is performed under local anesthesia and with care even the pain resulting from the first prick of the needle can be eliminated. The patient's face is cleansed with alcohol, and iodine is applied over the nose and upper hip.

Anesthesia A 10 per cent solution of cocaine is used to anesthetize the nasal mucosa, a 1 1,000 solution of adrenalm is applied to supplement the cocainization and to minimize the bleeding. Then the entire intranasal field of operation is indimized. The iodine is immediately neutralized by a liberal application of alco.

Fig. 1. Humped Nose before and after operation. Nose straightened and shortened. Post-operative picture taken two weeks after operation still showing slight swelling in the lip.

hol. A 2 per cent solution of novocain containing adrenalin is used for infiltration, which begins at the base of the columna nasi and passes outward to the tip and upward along the top of the septum and bilaterally over the bony structure of the nose.

Technic. The scalpel is passed up through the nostril and an incision is made between the upper and lower lateral cartilages and extended laterally over both the nasal processes and downward along the top of the cartilaginous septum. The entire incision is made in-

Fig. 2. Long Nose before and after operation.

side the nose, the skin is not cut at any point. The tissue over the bridge of the nose is loosened, and before the nasal bone is removed, the periosteum is pushed back and saved. The excess of bone is removed by saving, and the nasal processes are leveled by paring with a rasp. The septum is trimmed and leveled with a cartilage kinde and shortened, usually by the removal of a V-shaped section from the tip or center, according to the structure and position of the

cartilage Two or three silk sutures are

passed through the septum and adjoin-

ing tissues for the purpose of closing the gaping space

A broadness of the bony structure of the nose may be corrected by detaching the nasomaxillary processes by means of a saw or chisel, and pushing them medially If the tip of the nose is too broad, sections may be removed from the superior edge of the lower lateral cartilages to facilitate the narrowing process A soft metal splint is placed on the nose for 48 hours. The splint minimizes the postoperative edema, prevents discoloration of the eyes and molds the nose The splint should be tightened every 12 hours because it separates to some extent as the tissues swell However, this is an advantage in that it is fool-proof, $i \in I$, it is rigid enough to minimize the edema but flexible enough to prevent sloughing of the skin

The pressure upon the rasal bridge gives this splint a decided advantage over

all other similar appliances

In the cases with collapsed alae (previously mentioned) the operative procedure is the same except no tissue is trimined from the borders of the lateral cartilages. Instead, during the shortening process, the lower is allowed to slip up over the inferior border of the upper lateral cartilage, thereby re-enforcing the supports of the alae. The average period of hospitalization is 48 hours.

After the first 48 hours the dressing consists of adhesive strips. It is used chiefly to prevent public inspection and criticism until the swelling disappears. For the first few days patients are very solicitous concerning the length of the nose, since, because of the swelling, it appears entirely too short. As the swelling recedes, the tip of the nose drops to

normal and the patient's anxiety is relieved. Peroxide of hydrogen may be used for cleaning and keeping the nostirls open. The sutures are removed on the eighth to eleventh day, according to the healing ability of the patient.

During the operative process the fissue is loosened over the bridge of the nose to let the skin contract and this return to its original firminess over its diminished contents without puckering. The periosteum over, the nasal bone is saved and pulled downward over the leveled processes, because the bone regenerates beneath it to form a straight bridge almost as strong and thick as the previous one

Results The shape of the nose is well migh perfect and the breathing is always improved, and, if the patient has a neurotic tendency, it is relieved in proportion to the plastic improvement

Long Nose

The reconstructive process in this case is the same as that for hooked nose, except that there is no hump to be removed

Crooked Nose

The crooked nose is of traumatic origin and its severity depends upon the fragility of the nasal structures and the force with which the injury was received. It usually presents a complicated surgical problem owing to the abnormal positions in which the small fragments of the supporting framework heal following violent displacement of the parts. The absorption of some parts and the cicitricial contractions of others are ever present complications In this type of cases the nose is deformed laterally The defect is greatest when both nasomaxillary processes are fractured with subsequent healing before attempting to correct the displacement Then the deformity may be considered bilateral 1e, both processes or sides of the nasal framework are displaced in the same direction. The absorption and cicatrization are least when the osseous framework of the nose is most sturdy In adults, regardless of whether one or both nasomaxillary processes are in volved in the defect, both processes are detached before forcing them medially In children under 14, it is not wise to attempt any corrective measures which

Crooked Nose before and after operation. Intranasal structure reconstructed and straightened.

might interfere with future nasal ventilation. In the young, the processes, due to their flexibility, may be forced laterally or medially to their normal positions by means of proper instrumentation. This avoids detachment of the processes and

promotes more normal development of the nasal chambers.

The operation for this type of nose differs but slightly from the routine described for the hooked nose. After removing the hump on a crooked nose the

in reconstructive process. Broad tip made narrow.

Fig. 4. Saddle-back Nose before and after operation. Cartilaginous graft from rib utilized

nasomivillary processes are detached at their bases by using either a saw or a chisel Then the cartilagmous septum is incised against any concavities to break the springlike effect of the cartilage. The meisions pierce the mucous membrane and pericondrium of the concave side as well as cartilage proper The mucous membrane and pericondrium of the convexed side are left intact. The septim is then straightened and shortened, as previously described. The nose is molded and the metal splint put in place The splint is removed after 4 or 5 days

In detaching the masomaxillary processes, some surgeons prefer a clusel, others a saw The writer has always considered the nasal bones too fragile for the use of a chisel, moreover, the saw is under much better control and the patient does not suffer from the shock of the blows, which may prove very unpleasant in the case of nervous patients

Saddle-back Nose

This type of deformity varies from other types in that it may result from one or more causes Although not confined to any race or profession, it is more noticeable among races having well elevated nasal bridges. The following types and causes have been noted. (1) Congenital, with hereditary syphilis or endocrine disturbances, (2) traumatic, with injuries or faulty submucous resections, (3) pathological, with tertiary stage of acquired syphilis or tropical and oriental infections such as gangosa, frambesia, espundia oriental sore

In the author's experience a third of these cases result from congenital syphihs Among the cases due to endocrine conditions were 2 of chrondrodystrophy, correction of the nasal deformity in these patients was not attempted, since it was of such minor importance. A case of pituitary or possibly multiglandular involvement, having only 4 upper and 2 lower small, pointed canine teeth, was operated upon and referred for dental prosthesis. The best results in endocrine cases involving dental maldevelopment and in syphilitic nasal deformities accompanied by perforation of the hard palate cannot be had without the co operation of a dentist possessing great patience and unlimited ingenuity. In perforations of the hard palate, proper mechanical protheses assist in restoring nasal and oral functions as well as in normalizing speech which is usually affected in these cases

Injuries resulting from games, sports, and industry are only slightly ahead of faulty submucous resections as a cause of flat nose Congenital and traumatic causes are encountered in deformities among patients between 12 and 35 years of age, while pathological conditions produce deformities most often in patients past 35 years of age However, the writer has seen one case, thought to be oriental sore, in a Turkish girl of 24 Pathological deformities of this type are the most severe of all and as an added difficulty present considerable scar tissue Plastic reconstruction should not be considered without first determining the ab sence of all pathological organisms as well as all active pathological processes In the saddle-back nose the nasal crest is pushed posteriorly and the nasal tip is slightly elevated. The elevation varies in accordance with the severity of the deformity of the nasal bridge

Technic First, a plaster-of-paris cast is made of the nose and dental wax is molded into the concavity, until the nose has attained the shape desired after operation. Then, the wax model is taken to the operating room A piece of costal cartilize with its pericondrium is removed under local anesthesia, routine method, and shaped like the wax model but somewhat smaller, because the model fits outside the skin while the trans planted piece goes beneath. The tendency of the cartilage to turn up at the ends can be overcome by cutting the pericondrum criss cross

By routine method, an incision is made intranasally along the lateral cartilage and the skin loosened well out over the nasal processes. The transplanted piece, which, when properly shaped, is introduced through the meision, fits the nose as snugly as a saddle. The incisions are made on both sides and of course they must be the same length to assure symmetry and uniform contraction. No splint is used in this type of case three small black silk sutures are employed to close the incisions and a very light dressing is applied. The sutures are

26

KEITH KAHN

removed on the fourth to sixth day. Tf the patient suffers from syphilis or some endocrine disturbance, a silkworm drain should be inserted to drain off the serum which always collects in such cases. The site from which the graft is taken should receive routine surgical care. The period of hospitalization is 4 to 6 days.

Broad or Fat Nose

The broad or fat nose seems to be congenital. It occurs most frequently in, and characterizes the dark races. In the white races this condition indicates to some extent, a slightly unbalanced endocrine system. The osseous and cartilaginous framework of the nose is lacking in structural and anatomical development in all dimensions. The alae cartilages are thin, but the soft tissues covering them both intranasally and extranasally are very thick in the colored races. However,

The executive officers of fifty leading health and welfare agencies and groups of agencies representing close to one thousand separate health and welfare institutions and organizations in the five boroughs have sent a letter of congratulation and gratification to Mayor LaGuardia of New York City, hailing his instructions to the Commissioner of Hospitals, Dr. S. S. Goldwater, to proceed with plans for a modern hospital for chronic diseases on Welfare Island as the first step toward the solution of one of the most press-

Dr. M. E. Binet, vice-president of the medical society of Vichy, France, will visit the United States early this year to extend an invitation to several American physicians to attend the International Congress of Hepatic Deficiency which will be held in Vichy in 1937, presided over by Professor Maurice Loeper, Professor of Clinical medicine at the Faculty of Paris.

ing public health problems of today-the

care of the chronically ill.

The State Department of Health maintains a large supply of "silent" health motion picture films in both the 16 and 35 mm. sizes which are lent without charge for group showings within the State. A complete list of the films available, together with a synopsis of each and statement concerning conditions under which they may be borrowed, will be furnished on request by the Supervisor of Visual Public Health In-struction, State Department of Health, Albany, New York.

in the yellow races the soft tissues are normal in development.

Technic. This type of nose is revamped in the same manner as the saddle-back nose. However, external incisions may be necessary to narrow the nostrils. For this reason it is impossible to standardize thoroughly the operation and each case must be handled individually.

In the author's series of cases it has been comparatively easy to establish a definite neurosis and to recognize plastic surgery as a means of giving peace of mind and happiness to such patients. One case of hay fever and several cases of chronic headache supposedly of sinus origin but with negative x-rays of sinuses-were relieved. No explanation is offered of these results, though it is conceivable improvement of nasal ventilation and drainage effected the relief.

769 SEVENTH AVE.

The incomplete indexing of current medical literature has reached a critical point, said Charles Frankenberger, Librarian of the Kings County Medical Society, in his presidential address at the convention of the Medical Library Association in Rochester. He remarked:

"As the knowledge of what other investigators have done is a primary step in all experimental work it seems logical that the existence and maintenance of a complete index to medical literature is of vital importance to all research and that a part of the funds of foundations and institutions conducting experiments and studies might be contributed toward sustaining and making possible the more complete indexing of medical literature."

The fourteen living founders of the Rochester Academy of Medicine were honored at a dinner celebrating the Academy's 35th anniversary on Dec. 7. Over two hundred were present. The principal speaker was Dr. John A. Hartwell, Director of the New York Academy of Medicine.

Eleven of the original founders still living in Rochester are Drs. Edward B. Angell, William M. Brown, Robert Carson, George W. Goler, S. Case Jones, Marion Craig Potter, E. Wood Ruggles, Henry T. Williams, Frederick W. Zimmer and Charles D. Young. The others are Dr. Horace J. Mann of Brockport, Dr. Robert Cook of Canandaigua and Dr. Charles T. LaMoure of the Mansville State Training School, Conn.

THE SURGICAL TREATMENT OF CORNS

WALTER I. GALLAND, M.D., New York City

The attitude of the surgeon towards the common corn or clavus has long been one of utter indifference, giving the laity the very definite impression that this condition is far beneath the dignity of a respectable surgical practice. In consequence of this attitude, the treatment of this ailment has been relegated to the hands of a quasi-medical profession.

In 1933 I published a short article on an operative treatment for corns, and since this publication a continued experience in the development of this procedure has convinced me that much useless suffering, which is usually only temporarily alleviated by the palliative treatment of the chiropodists, could be effectively prevented by the use of a surgical procedure designed to eliminate the basic pathological conditions which favor the persistence of the clavus.

In the usual text, clavus is considered merely as a circumscribed hyperplasia of the corneous layers of the skin with extensions going down as far as the corium. It is a structure which is usually pared away or which is softened by the keratolytic applications frequently employed. This cornification, however, is only the superficial manifestation of the clavus, and its elimination does not touch the basic pathological condition which will inevit-

ably reproduce the corn.

The clavus is commonly found over an interphalangeal articulation. It is a manifestation initially produced by friction with a shoe, but coincident with the irritation of the skin, there occurs an irritation of the underlying tendonous and articular structures. In response to this deeper trauma, the tissues react in the expected manner. Between the skin and the tendon, a bursal structure appears and with continued friction this may grow to appreciable size, and may at times become infected. This bursa is situated directly over and lying upon the extensor tendon. The articular margins of the phalanges, stimulated by the same chronic irritative influences, behave as joints elsewhere react to traumatic influences. Hypertrophic

lippings arise from the juxta-articular margins of the phalanges, and with this growth there appears a new factor in the etiological train, for the bony excrescences have now formed, constitute counterpoints of pressure between which and the overlying footwear, both the skin and the bursal structure are constantly traumatized. For the permanent relief of clavus, therefore, we must consider three structures-the cornified epithelium, the underlying bursa, and the juxta-articular eminences of the phalanges. (Fig. 2.)

The soft corn which appears between the toes is very similar to the clavus described above, except that the cornified skin is continuously macerated by the moisture which gathers between the toes. The bursal structure is less apt to be present, but the bony excrescence can always be found, and constitutes the principle source of friction. A peculiar deviation from the pathology noted above is sometimes met with in the soft corn. It will frequently be noted that the osseous prominence exists upon the phalanx of the adjacent toe and not under the corn itself.

Operative Procedure

The preoperative preparation of the skin is important, for the feet are apt to be grossly contaminated by organisms which have become deeply embedded in the cornified epithelial layers. Due precaution should be taken prior to operation to overcome any active fungus infection. It is advisable to have the feet thoroughly scrubbed with soan and water on several successive days prior to operation.

The operation is performed under local anesthesia. In order to avoid infiltrating the corn area itself, and thus obliterating many of the anatomical details, I have employed a block anesthesia using two per cent pro-caine with adrenalin. Seven cubic centimeters of this solution has usually proven adequate to secure a complete blocking of a single toe.

After the usual skin preparation the cornified layers of the clavus are removed with a

sharp curette. It will be found that this portion of the clavus peels off quite readily

[Volume 36

without entering the vascular layers of the skin. When this has been entirely removed, the skin is again iodized and a semielliptical flap is outlined surrounding the corn.

In my earlier operations, the skin flap was

made as would have been normally expected, with the base of the flap situated proximally. However, in several cases thus operated, although the corn did not reappear, the skin continued to exhibit a tendency towards

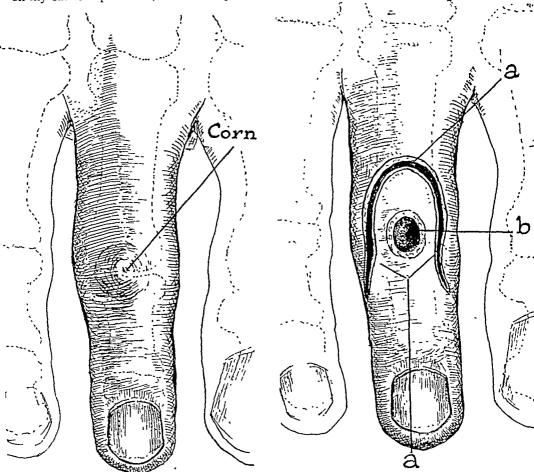

Fig. 1. Diagrammatic illustration showing the usual location of the common corn over the interphalangeal articulation of the toe.

Fig. 3. The usual skin incision with the base directed distally. b—Cornified area has been curetted prior to making the incision for the flap.

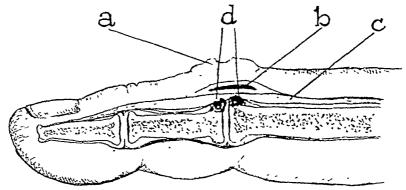

Fig. 2. Sagittal section through the corn showing the component factors producing the phenomenon. a—Cornified epithelium. b—Bursal sac. c—Extensor tendon. d—Juxta-articular bony prominences which constitute the points of counter-friction.

hyperkeratosis, and as a result a rather indurated integument covered the area. In the later cases in order to obviate this difficulty, I have outlined the skin flap with the base placed distally on the supposition that such a flap would tend to have its circulation considerably diminished, and that the skin of such a flap with its reduced circulation would show a diminished tendency towards hyperkeratosis. The results have justified this procedure, and there has been no serious difficulty in securing viable skin flaps with his incision. The base of the flap should flare outward, so that the connecting isthmus will not be too narrow to permit adequate vascularization. (Fig. 3.)

When the skin flap is dissected back, the bursa will come to view quite promptly. At

Fig. 4. The skin flap has been turned back. The bursa (b) is seen overlying the extensor tendon—a. Occasionally this bursa adheres to the skin flap at point indicated—c.

times this structure is difficult to define, and is represented by a small mass of synovial tissue which overlies the extensor tendon. At other times the bursa is quite large and may contain calcified material or inflammatory exudate. The bursal structure is renoved leaving the clean surface of the extensor tendon. (Fig. 4 and 5.) An incision is now made alongside and parallel with the fibers of the extensor tendon. This incision extends down to the articulation and should be long enough to traverse the entire articular area. (Fig. 6.) With a small periosteum elevator the tendon and periosteum are pushed to one side exposing the articular

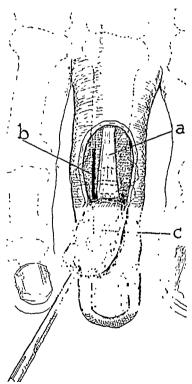

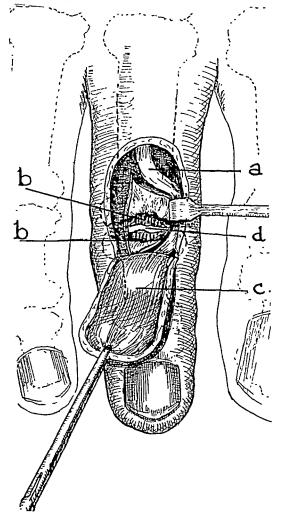

Fig. 5. The bursa has been removed leaving the clean surface of the extensor tendon. The capsule of the articulation has been incised along the line—b.

margins of the phalanges. (Fig. 6.) Usually the bony excrescences are immediately apparent, but occasionally they will be found quite far laterally or medially in the wound area, and if not evident on inspection can be readily located by digital examination of the joint margins. The bony prominences are then removed with a very fine chisel. Due care must be taken to remove enough bone. The juxta-articular margins should be well beveled, and any prominence should be thoroughly smoothed down so that a depression exists in place of a prominence. This eliminates the possibility of a persistent osseous point of counter-friction.

The wound is closed in layers using 000 chromic gut in the joint capsule and silk

The extensor tendon—a has been displaced exposing the articular margins. juxta-articular prominences—b are thus brought into view. d—the joint space. The prominences should be carefully removed so that no excrescences remain along the articular margins.

sutures in the skin. No splinting of the toe is necessary. The patient is usually able to walk with a cut-out shoe after the first day and may expect to wear such a shoe for a period of three to four weeks before the area is sufficiently insensitive to permit the use of an ordinary shoe. For women, the now commonly worn sandal shoe lends itself very well to this purpose.

The operative procedure outlined above is not always applicable to the treatment of soft corns. On those corns which are deeply situated between the webs of the toes it is not possible to carry out this operation satisfactorily. In such cases, after curetting the clavus, I completely excise the cornified area in the web, remove any subjacent bony prominence and effect a closure of the wound by undermining the skin edges and drawing in the redundant tissue in the web between the toes. An easy closure can thus be made without undue tension.

Results

This operation has now been used for the past four years without any complicating incident of moment. In one case, that of a male patient, there was a slight necrosis of a portion of the skin flap. This particular corn would probably have been best operated with a flap with the base situated proximally, inasmuch as the skin over the area was obviously extremely indurated and paper thin. In future cases of this nature I should suggest that a flap with the base proximally should be used. No infections have been encountered and without exception these patients have been able to walk around with a fair degree of comfort within four days after operation. Several interns and nurses operated on for corns have continued their duties without interruption following this procedure.

Conclusions

- 1. The ordinary clavus is amenable to operative treatment.
- 2. The operation must eliminate the factors which produce the recurrence of the clavus—the hyperkeratosis, the bursa, and the juxta-articular prominences.
- 3. The operation is simple and devoid of any great risk of complications.

EDITORIALS

The New Year

We approach the new year with confidence and courage Our past is not unworthy Our tradition is still our pride During the depression which seems to be lifting, medicine has done its share. No one, anywhere who needed and asked for medical care was denied it. That part of the profession which itself suffered want and deprivation, met its burden with calm and confidence, took medical work where it was to be had, and is emerging stronger and better.

The everpresent struggle to keep the tradition of the profession infact, maintain confidence between patient and doctor, is not lost to us Attacks upon our Jong established code of ethics have not intpressed upon us the necessity of changing that which from ancient times was devised for the patients' welfare. We are still embattled, but with our lines "firmly held," endeavoring to maintain the individualism of private practice, and to give all the benefits of private practice to the less fortunately placed, and the under privileged groups in the population. We have devised changes in the medical as pects of the Workingman's Compensation Law that seem to hold out benefits to both the injured workmen and the physicians, to the general welfare of the community

As a people, and as a profession we still are free!

Safety Brakes

President Roosevelt is showing that he understands the value of brakes as well as accelerator in driving the car of state. His decision to limit the program of the next Congress to essential business will relieve the anxiety of many who feel that the government is going too fast and too far over untried roads. Nothing will be lost—and much may be gained—by a period of critical observation in which desirable reforms may be consolidated and mischievous innovations dropped.

Undoubtedly the President's decision means that no action will be taken on compulsory health insurance at the forthcoming session—a respite for which the country as a whole no less than the medical profession has reason to be grateful Many of the experiments essayed in the past two years have shown such a wide divergence between theory and practice that the nation is disposed to proceed cautiously with new reforms, particularly in a field like medicine, which had made notable advances and cultivated a lofty tradition without governmental control

The profession does not doubt the sin certify of Mr Roosevelt's desire to place our social and economic system on a siner and sounder basis. Many of its members are in full agreement with the

need for far reaching reforms. As a body accustomed to controlled scientific experimentation, however, it cannot accede to the large scale application of unproven theories or to the progression from one innovation to another without an interval to observe and analyze the consequences of each.

A number of Mr. Roosevelt's policies, for example, were actuated by the desire to bring about a more equitable distribution of wealth; but his most enthusiastic supporters will not deny that recovery so far has taken an opposite direction. In the past year there has been an appreciable rise in the incomes of the rich but the living standards of the lower and middle classes have dropped. The theoretical benefits of compulsory health insurance have failed similarly to materialize in Europe, where introduction of this system has nowhere been followed by the promised decrease in morbidity and mortality or increase in disease prevention. This failure of actuality to conform to theory is not attributable to incapacity on the part of those directing the experiments as much as to the inherent difficulty of incorporating socialistic practices in a capitalistic state.

Mr. Roosevelt apparently knows how to blend realism with idealism and is not afraid to call a halt when some of the theorists surrounding him get out of hand. It is to be hoped that he will not permit anything as essential to the public welfare as medical service to be tampered with until bureaucratic control of private enterprise has given a better account of itself than it has so far.

Blue-Printing Social Problems

At the anniversary meeting of the New York Academy of Medicine, Mr. Walter M. Lippman made some very pertinent remarks anent the tendency to make blueprints of a social problem and proceed like an engineer or an architect to apply remedies.

His thesis was "that statesmen had better think of themselves as physicians who assist society than as engineers who plan and fabricate it."

Medicine, as has often been shown, in the form that it is used by the people, is modified by the form of the society it serves. In the approach to problems concerning medical care, and its delivery to all groups of our people, it follows therefore, that no one scheme or plan can possibly be made applicable to the whole country.

To those entrusted with the problems of finding solution to the pressing problems of medical care, Lippman's words hold an important message. He decries the ruthlessness with which, engineerlike, those who would plan society, cut human nature to the shape they desire and nail together in a design of their own, the living spirit of men.

Income and Health

Organized medicine has frequently pointed out the relationship between income and health, insisting that no system of medical care can compensate for insufficient food, inadequate clothing, and scanty housing. Of late this point of view has been taken up by social welfare workers, no less an authority in this field than Mr. Edgar Sydenstricker agreeing on the importance of economic security as a preventive of disease.

Mr. Sydenstricker does not carry his idea to its logical conclusion, however, when he puts social insurance in the same class as increased earnings as a means of providing economic security. "To what avail is it to send a nurse to instruct a mother," he asks, "when that mother cannot pay for a physician?" To what avail is it to send a physician, we add, if weekly payments for compulsory health insurance lower the living standards of the small wage earner and reduce already meagre allotments for nutrition and housing?

As long as millions of people continue to live in disease breeding slums and subsist on a third grade diet, it is useless and illogical to talk of preventing illness by compulsory health insurance. The boasted American standard of living has been shittered beyond recognition in the past six years—and in its place the country is offered an expensive bureaucratic pallintive for the consequences of poverty. When will labor realize that its direct and indirect payments for compulsory health insurance would lower living standard still further and condemn the small wage earner to a state of perpetual proletarianism?

Postgraduate Instruction by Detail-

Within recent years there has arisen a new type of postgraduate instruction in therapeutics which literally has been forced upon the medical profession. We allude to the high pressure sales talk of the detail men attached to some of the pharmaceutical houses and to concerns manufacturing apphances for physical therapy Equipped with but a smattering knowledge of the few medical topics in which they are interested, these men presume to educate the physician as to the inadequacy of his present means of treatment when compared to the drug or apphance which they are selling When unsuccessful in convincing a doctor by their pseudoscientific discussion, they in variably point out to him the increase in monetary income which is bound to follow his purchase of this or that machine Advocating that he use intravenous medication because it necessitates many more visits on the part of the patient, they try to enlist his use of their product by this bait They attempt to inveigle a doctor into the purchase of an expensive appa ratus, whose use is not understood thoroughly as yet, by citing garbled reports of scientific publications or by telling him that his nearest competitor has seen fit to install one All this is objectionable to the largest number of medical practitioners

All forms of therapy which are advocated have been and are being subjected to rigid experimentation by the profession before an opinion is expressed as to their value in the treatment of disease. The physician rightly looks to his medical conferers for authentic opinions on the newer forms of medication and he finds them expressed in medical publications and at the stated meetings of scientific societies. The fine relationship which has hitherto existed between the ethical pharmaceutical and other concerns and the medical profession should not be jeopardized by the desire of sales organizations to foist untried or at the best, poorly tried remedies upon the doctors.

Salvarsan, insulin, avertin, to mention a few medicaments, and drithering my clinies, quartz lamps and radiothering appliances are sold purely as a result of the knowledge gleaned by the profession after long experimentation. Their limits of application are known and their worth proven, and these articles sell themselves. The less well proven, and those whose use implies more visits and more money only for the doctor hardly ment consideration at all.

Effect of Placental Extract on Dick Test

The problem of conferring immunity against the contagious diseases is still the active concern of many investigators. While in themselves, searlet fever, measles, whooping cough, et cetera, are self limiting diseases which run a mild course, their potentiality to involve vital organs with eventual lasting impairment to them, often resulting in loss of life, represents an important factor in the mortality rate of a community.

Most of the experimental work in this field has been done with vaccine, anti-toxin and antivirus, although lately human blood has been found to possess immu nologic properties when injected intra-muscularly. Attention also has been directed to the fact that extracts made from the placenta contains immune bodies. McKhann and his associates have studied

¹ McKhann C F Green A A Eckles L E and Dayles J A V Immunological Applications of Placental Extracts Effectiveness by Oral Administration Ann Internal Med, 9 388 Oct 1935

the value of these extracts in the prevention of scarlet fever. Their investigation embraced not only the efficacy of placental extract when injected hypodermically but also when administered by mouth. In twenty-two children in whom the Dick test was positive a reversal of the reaction was obtained following the ingestion of a cold aqueous solution of the extract. The duration of this negative stage varied. In some instances the Dick test remained negative for as long a period as eighteen days. The authors note that the period of negativity was prolonged when the placental extract was given in iced alkaline carbonated water on an empty stomach. They were unable in adults to convert a Dick positive into a negative reaction.

The field of immunology is broadening constantly. From the study of the immune properties embraced in human tissue it may subsequently be found that the lack or loss of certain active substances in the body may account for the susceptibility of an individual to some of the contagious diseases. McKhann's report shows that in children, at least, the clinical evidences of susceptibility to scarletina temporarily disappeared when the immune bodies of placental extract were added to the body.

In All Fairness

In its last issue this JOURNAL commented unfavorably on the administrative requirements of the Federal Resettlement Administration, of which Rexford G. Tugwell is Director. Criticism was based on a report in the New York Times in which the Resettlement Administration was said to have engaged over twelve thousand administrative employees to five thousand and seventy-two relief workers.

Since then, Mr. Tugwell has pointed out certain inaccuracies in the *Times* report. While the Resettlement Administration has employed only 5,072 relief workers to date, it is in addition caring for 354,000 farm families, its program being "primarily one of rehabilitation rather than of direct work relief. * * * Instead of two administrative jobs for

each relief job, there are twenty-eight cases receiving work relief or rehabilitation under the Resettlement Administration for every person on the administrative pay roll."

While one administrative worker to twenty-eight cases still seems like a high ratio, there is a tremendous difference between this and previously published figures and the Relief Administration is entitled to a frank admission of error. The New York State Journal of Medicine regrets the mistake and is pleased to publish the corrections supplied by Mr. Tugwell.

CURRENT COMMENT

IN THE OCTOBER 1935 issue of Law and Contemporary Problems Dr. Frederic E. Elliott and Dr. Ramsay Spillman, writing on "Medical Testimony in Personal Injury Cases," says "It is our belief that in a very large percentage of the negligence claim cases, in which we have had personal experience, a simple arbitration hearing could have been arranged promptly, and a satisfactory conclusion of the case established to the economy of the tax-paying public (who support the court), the economy of time of the physicians and other witnesses (who are called upon to appear), and to the ultimate betterment of both parties to the litigation, and to their attorneys. If either the plan which we regard as ideal or the proposals which we offer as compromise substitutes therefor were adopted, the number of cases handled by informal arbitration would, undoubtedly, be vastly increased."

Speaking of Public Housing, Raymond Moley, in *To-Day* of December 14, 1935, among other things says, "No one in America ever builds a new one-family house on a site vacated by another, unless it has burned down. This constantly draws people away from the built-up central areas.

Now the retreat of the pleasant residential sections farther and farther from the blighted centers of cities, which will be accelerated by a private residential boom, is a socially desirable movement. But we ought not to forget the predicament of the cities left behind. Unless we continue our efforts to find a way to maintain or rebuild the health of the central areas we will have on our hands bankrupt cities which must support public services only partially paid for."

IN THE St. Louis County Medical Society

35

Bulletin, we find the following from the pen of Dr. Eben J. Carey. "I am afraid that there are still physicians who look upon medical economics as an intricate subject which few can understand without pondering it as one would an income tax report, thereby adding a few more gray hairs. This perhaps accounts for the indifference towards this subject that still exists, although the situation is rapidly improving.

There are, of course, a large number of physicians who are interested in this subject. Undoubtedly it was due to their efforts that the American Medical Association created its Bureau of Medical Economics which has been in existence some two or three years. The Association's experience confirms the helief expressed that although there was a demand for active participation of the Association in medical economics, once its Bureau was established there was not the general interest and enthusiasm which was expected."

Dr. Harrison Betts, in an address made when he retired from the office of President of the Medical Society of the County of Westchester, as published in the Society's Bulletin, summed up the problems confronting organized medicine into five major problems. To stress their significance, we republish Dr. Betts' summation. "First, the relationship between the private physician and the hospital clinic and the question as to who shall ultimately control the clinic:—

the hospital, the social worker, or the

physician.

Second, the relationship between the private physician and the department of public health, and the problem of restoring the practice of preventive medicine to the physician.

Third, the financial relationship between the private physician and his private patients, and the problem of assisting people of moderate means to meet their obligations for medical service without hardship.

Fourth, the relationship between the private physician and the welfare departments

and welfare clients, and

Fifth, the relationship between the private physician on the one hand and the employers, employees and insurance companies on the other,—in compensation practice."

IN THE New York Sun of December 7, 1935, George Van Slyke calls attention to an astounding speech recently made by Aubrey W. Williams, who is director of the new youth movement, known as the National Youth Administration. This speech has aroused the educational world to a realization of the alarming trend of that venture, and stirred politicians to a comprehension its potentialities as a vote-getting medium. With this political point of view we are unconcerned. We must ponder over the idea promulgated by Van Slyke, however, when he implies that the philosophies of Stalin, Hitler, and Mussolini in composite form are taught to our youth.

December 3, 1935

New York State Journal of Medicine, 33 West 42 Street, New York City.

Dear Sirs:

In the article of the December 1 issue of this Journal by S. N. Kritzalis on "Gonocomenia with Complete Recovery" a very incomplete review of the available literature on the value of blood transfusions for this type of illness was made.

In the May 1930 issue of the American Journal of Medical Science, p. 559, Perry

reported a case of "Gonorrheal Endocarditis with Recovery" in which he emphasized the value of frequent blood transfusions.

Very truly yours,

Samuel S. Adler, M.D. 110 Riverside Drive New York, N. Y.

Perry, Matthew White—Gonorrheal Endocarditis with Recovery, Amer. J. Med. Sciences, May, 1930, p. 559 [correct page number 599].

DR. HENRY B. SMITH, of Hempstead was made president-elect of the Nassau County Medical Society at the November meeting.

Dr. Louis H. Bauer, of Hempstead, was elected vice-president; Dr. Herman Wahlig, of Sea Cliff, secretary-treasurer, and J.

Louis Neff, executive secretary. They will serve with Dr. Phipps, president for 1936.

Dr. Alfred Shipley, deputy Hospital Commissioner in New York, gave an address on workmen's compensation medical practice.

Medical Economics

Subtle and persuasive forces are at work influencing the public mind in favor of state medicine, and its substitutes, socialized medicine and compulsory sickness insurance.

High-school debating teams throughout the country this year have chosen as their subject: Resolved, That the several states should enact Legislation providing for a System of Complete Medical Service Available to All Citizens at Public Expense. This subject was selected by the Committee on Debate Materials and Interstate Cooperation of the National Educational Association.

This means that throughout the country, in secondary schools, and in associated circles, this question is continual discussion. It is estimated that 8,000 high schools are to participate, with audiences totalling a million persons. Debaters are supplied with plenty material, affirmative and negative, from well-organized sources.

Professor Bower Aly, of the University of Missouri, is the editor of the Debate Handbook on the subject "Socialized Medicine" and the material he presents in a two-volume work on the subject is not confined to the major proposition, but also contains arguments pro and con on compulsory sickness insurance. The handbook is published by Lucas Brothers. Columbia, Missouri, at the price of \$1.50 for two volumes.

Mr. J. Weston Walch, Debaters' Information Bureau, 45A Free Street, Portland, Maine, edits the "Complete Handbook on State Medicine" a comprehensive collection of notes and references on both sides of the question. It sells for \$2.50 and cumulative supplements are issued monthly.

Both these publications are carefully prepared as to both sides, and are valuable as a source of reference to those wishing to maintain the contentions of organized medicine on the subject.

The two-volume handbook published by Lucas Brothers, besides briefs, hints and helps to debaters, contains several complete articles on the subject, both affirmative and negative. Michael Davis of the Julius Rosenwald Fund, Edgar Sydenstricker of the Milbank Memorial Fund, Joseph R. Slavit of the Medical League for Socialized Security are presented bearing on the affirmative, and on the negative side there are special contributions by Dr. R. G. Leland and Dr. Morris Fishbein of the American Medical Association, Dr. Wingate Johnson, and Dr. Frederic E. Sondern, president, Medical Society of the State of New York.

By permission of Professor Aly, editor of the handbook, Dr. Sondern's contribution to this symposium, "Medicine and Men," is published here for the information of the physicians of New York State.

MEDICINE AND MEN*

A Discussion of Compulsory Sickness Insurance

Frederic E. Sondern, M.D.;

In times of great economic stress and hardship, when we are called upon by the inexorable rotation of events to pay for past excesses, it seems that the penalty is too cruel to bear, that it is inequitably exacted, that some easy way to escape it can be found. It is in such times that we look with

the unfortunate and especially the sick who are unable to pay the cost of illness. Moved by commendable sympathy and zeal, certain sociologists and social workers are proposing such cure-alls as compulsory sickness insurance, advocated as a way to bring adequate medical care to all the people. It is my purpose here to discuss this scheme, which has incurred the almost universal condemnation of the medical profession, the

sympathy and commiseration on the lot of

^{*} Prepared for the Debate Handbook. All rights reserved. (Reproduced by permission.) † Editor's Note. Dr. Frederic E. Sondern is President of the Medical Society of the State of New York.

very men who would be called upon to make it effective, and who judge it in the light of their experience with medicine and men.

I believe I speak for the medical profession when I say that we are moved deeply by the spectacle of people in need, and I may add, what later I shall refer to again, that we have continuously throughout the depression and even before, offered our services unstitutingly in the alleviation of the miseries of those who are unable to pay for medical care, as well as those able to pay only part of its cost. This is a traditional, historic obligation. The medical profession of America has met this responsibility within the last five or six years in a creditable manner, to the point of severe individual financial sacrifice, thus accepting its share of the catastrophe which has descended upon all of us.

So well has this emergency been met under the prevailing system of practice that it can be said that there is little lack of medical care if the person needing it, or his family, will seek it. This may not be true in isolated sections of the country, or in sporadic instances, but in general it is true among the majority of our population. Physicians do not eject patients from their offices because they do not have cash in their hands, nor do clinics close their doors to them. If the patient cannot pay the doctor in full, he pays less; if he has nothing, he is treated without cost or is referred to institutions which care for indigent patients, This is always the case if the patient seeks medical care; if he does not can it he forced on him to good purpose?

But, it is claimed there is a lack of medical care generally in this country. It is made to look as if the medical profession, some way or other, is withholding from people the services it is their business to provide. This claim is based largely on the results of the periodic medical examination of school children and the medical examination of men drafted for war service, and on certain surveys of small population groups. These reveal without doubt large numbers of cases of poor health, defects which can he remedied, actual disease and medical neglect. Does this justify a belief that a system of compulsory sickness insurance would remedy the situation? It has not done so in any country where this system of medical practice is in operation.

Proponents of compulsory sickness insurance point to the fact that surveys have shown that almost half of the American people get no medical care whatever. But these surveys do not disclose what type of medical care these persons needed, nor whether they had sought it and why they failed to obtain it. So this fact proves nothing, except perhaps this: that almost half of the population are without medical care of a preventive rather than a curative type, doubtless because they are unaware of the value of preventive medicine, or are indifferent, or ignorant. We have no facts whatever from such studies as these showing that any percentage of the population whatever, desirous of medical care, and seeking it, are not able to get what they need and want.

Therefore, the problem is not to bring to their door something which as yet they do not feel they need, offered as a part of a compulsory system of medical practice, but the problem is to educate these people to know that they should have periodic health examinations, that they should consult a physician early when symptoms of disease appear, that the old adage is still true: "prevention is better than cure." Many of the advocates of sickness insurance are recruited from the ranks of health educational workers in connection with official or voluntary agencies. It is recommended that they concentrate on these health education programs, which are as yet unfinished, redoubling their efforts to create the desire for good health, and disseminating the knowledge of how medical aid can improve it, using those gradual processes of education which have been attended by sound and encouraging improvement in the past. This is wiser than to attempt, by an allinclusive scheme, to find a panacea for ills too various for a simple cure.

Before passing to the consideration of the proposed insurance law itself, let me say that if the experience of the medical profession justified the opinion that the system would result in adequate medical care for all of the people, they would be the loudest advocates of the measure. But medical men with few exceptions are opposed to the compulsory sickness insurance scheme. They believe it will not in fact, bring adequate medical care to those whom it serves, but an inferior quality of care to that which is at the disposal of the wage earning group today. Medical men believe the plan will result in a deterioration of the physician's standards of excellence, that it will foist upon society a bureaucratic system politically controlled, which will feed and fatten at the expense of the workman and interfere, to the great damage of the patient, with the relationship between him and his physician. These considerations strike at the very vitals of the profession. We are moved deeply by consequences which we envision in this country if compulsory sickness insurance becomes effective, and we find when we

travel in Europe where this type of practice has been established, evils which could not be avoided, and perhaps would be aggravated, here.

Let us examine, in general, the provisions of the law as it has been offered for legislative enactment in this country, under the popular name of the "Epstein" law. We shall discuss the results which may be expected to ensue from the establishment of the system in the United States, presenting some of the substantiating evidence from abroad, and analyzing the superior advantages of individualized medical practice over collectivist efforts.

The Epstein law was proposed for enactment in a number of state legislatures during the sessions 1934-35, and was passed by none.

The principal features of the law are

these:

Provision of medical care to all workers within a prescribed income class by "panel" doctors who are paid from an insurance fund.

The insurance fund is financed by contributions of a percentage of wages paid by the workman, another such percentage contribution by the employer, and a third by the state.

Administration of the law is by boards, councils and committees on which doctors, dentists and labor interests are represented, but the balance of authority reposes in non-professional persons.

The administrative set-up for the individual state described in the bill should open the eyes of those who believe that compulsory health insurance would lower the costs of medical care. At the top is the Health Insurance Board, consisting of a ten-thousand-dollar-a-year Director and three other members, each of whom would receive an annual salary of seventy-five hundred dollars plus traveling costs and incidental outlays. A State General Advisory council of twelve and a State Medical Advisory Council of nine would also be set up, each headed by a full-time finance and a full-time medical supervisor. Districts would be subdivided into local areas, each with its own full-time finance and medical managers. Aiding the local offices would be local councils, the members thereof receiving per diem fees in addition to traveling expenses. These councils, in turn, would be assisted by an unlimited number of local advisory committees, also entitled to draw incidental costs. For this involved bureaucracy (and only a meager skeleton has been sketched), the worker would pay in periodic deductions from his pay, in lowered wages and augmented living costs and in increased tax-

An independent investigation of the law was made by the Committee on Legislation of the New York County Lawyers' Association, which recommended disapproval of it in the following report:

"This bill seeks to establish a comprehensive state system of health insurance. Premiums are obtained by assessing every employer 3% of his payroll and the employee 1%. The benefits are of three kinds:

- "1. Cash for those disabled in any manner whatsoever.
 - "2. Maternity benefits.
 - "3. Medical benefits.

"The administration is placed in the hands of three members appointed by the governor and two members of the Health Department. State advisory councils, district offices, local offices, local councils and local advisory committees are created, and the procedure for hearings and appeals are provided. The amount of \$100,000 is to be appropriated by the state to initiate the system, but the state is to bear no further expenses.

"The bill incorporates the British compulsory health insurance system. Its purpose is to provide adequate infirmity and disability protection to indigent employees. The estimated per capita medical cost in this country is somewhat over \$30.00, and it is believed that by this method the needy would be assured of sufficient medical attention and infirmity protection.

"We believe the bill is open to serious constitutional objections. Contributions are assessed against employers who by themselves or in the course of their business have no causal relation to the conditions upon which benefits are based. To require every employer to contribute towards the expenses of an expectant mother who happened to be an employee,—or to require every employer to contribute to the maintenance of some employee who happened to be disabled through an accident entirely disassociated with his employment, would be violative of the fundamental concepts of the State and Federal Constitutions.

"Aside from the Constitutional aspects the bill is further objectionable. The principle of medical treatment "in gross lots" has never proved effective. Various systems allied to that of this bill have been in force for years in several European countries. The mortality tables there have revealed no improved medical conditions. The many annual administrative and other changes inaugurated from time to time in those countries reveal that the system is in a

perpetual state of flux and is not beyond the highly experimental stage. To change radically our lifetime method of medical antitention through personal choice and to eliminate the family physician" for an experimental system would be highly

unsatisfactory and unwise

"The bill will inevitably lower the stand ing of the medical profession. The majority of the doctors will be compelled to submit themselves to the bureaucratic control of a State Department in order to earn a livelihood. As past experience has demonstrated certain doctors would be favored in the amount of employment they would obtain and other doctors would be forced to different channels to support themselves. The zeal, the inspiration and the intellectual acumen of the medical profession so vital for scientific researches and experiments will be dampened considerably by the regimented control of doctors in the hands of a piternalistic State Department

Other objections need no elaboration. The severe assessment against employers would be economically demoralizing. The type of treatment and prerequisites necessary before such treatments are granted are not conducive to expeditious and effective medical attention. The bill further fails to place the control in the hands of the State Insurance Department where some degree of actuarial soundness of the system and efficient regulations therefor would be

assured

"However effective and however meritorious a system of coluntary health insurnce may be a state wide compulsory system would be the worst form of govern

mental paternalism"

The medical profession approaches the consideration of such plans as these with a background of knowledge and experience in view of which we ask respectful con sideration of our opinions. We are under a certain handican in the premises if we are to be required to submit our brief for the consideration of the general public, who have had no actual experience in giving medical care Some of the most serious of our objections are based on intimate knowl edge of our profession, they grow out of the unchangeable characteristics of human beings in the relationship of physician and patient It is not easy to make these objections fully clear to laymen without such knowledge and experience They are not so forceful when stated in print as they are when lived in life Our friends who believe that compulsory insurance will bring ade quate care to the people possess, on their side of the case, soothing gentle phrases of persuasion which simplify a matter which is really quite complex. As a stated problem on a piece of paper it may seem perfect. when it becomes an encountered problem m actual practice, the doctor who is to administer it, revolts. We look behind and beyond arguments such as this most half the people of the country get no medical care whatever, that masmuch as the average physician's income has been drastically reduced-therefore, "as is easy to sec"-all we have to do is to bring medical care to these persons who are without it by compelling them to insure themselves, and they will be well and happy, and the doctor's economic problem will be solved This may sound to'a layman as a self evident fact, and it is, the way it is put It perfectly fits our hopes and aspirations Now the physician is an idealist in his own way, just as the social worker is, but he is just a little more of a realist because his profession insistently, day after day, calls upon him to examine conditions objectively in terms of how things are going to work Not how they might work, please, if perfect conditions are presupposed, not how they o ight to work, with human beings making the desirable response but how they will work, actually, realistically, with human beings behaving as they do, and as they may he expected to do for some time to come

Let us observe what happens in European countries which have adopted this system I should like first to address myself to conditions in England, which have been

a matter of first hand observation

In England it is difficult for the panel physician to get all the facts from the patient The patient knows that the record made of his history and illness is inspected by the regional medical officer as well as by the insurance commissioner of the approved society. He is therefore guarded in his disclosures concerning himself, con trury, possibly, to his best interests. There are rigid restrictions as to the cost of drugs and appliances which hamper the doctor and affect the patient's comfort. Officials pry into details of the relationship which tends to lessen the patient's respect for the doctor Supervision of the panel doctor is exercised by divisional and regional medical officers These executives may be asked by the panel doctor to see patients for aid in diagnosis, or they may be asked to render the same service by the approved societies over the head of the panel doctor. In 1932, 626 853 patients were thus examined For the purpose of diagnosis, 42 were examined at the request of the panel doctor, while 1774 were at the request of the societies It is part of the English system that panel doctors shall certify a patient's incapacity

to work, in order for him to get benefits from the fund. It is astonishing to find that for purposes of certification, not diagnosis, requests for examination by superiors to the panel doctor were 3,348 at the request of the doctor, and at the request of the societies over the heads of the panel doctors, 621,689.

What is the conclusion to be drawn from this? Obviously that the non-professional element in the medical situation demands supervision of the panel doctor, only slightly for purposes of diagnosis, but extensively for the purpose of getting benefits for inability to work. It is not difficult to reconstruct the typical scene which in the natural course of things is enacted in many of these instances. The approved societies are interested in keeping down the costs of medical care; preventing losses from the fund, or possibly in getting favors or preferences for friends. Their viewpoint, as they inject themselves into the situation, is not medical. They exert pressure on the panel doctor to send a man back to work who has long been idle, or to get a man certified as still incapacitated whom the doctor might possibly consider well enough to work. So, under this system, the "boss" doctor is summoned. He sees the patient, and no matter what this superior may decide, the panel doctor has in a sense lost the confidence of the patient. Perhaps, in some cases, a better diagnosis may be the result, and in others, the decision as to whether the man can work or not, may be more just by reason of this supervision. But there are only a few appeals from the panel doctor's decision that the patient need not work; most of them are to keep him from having to go back to his job. And the glaring fact in the above figures which points an accusing finger at the whole system of compulsory insurance, is that these appeals for regional or divisional doctors to supervise the work of the panel doctor were so few for the purpose of diagnosis, so many for the purpose of affecting sick benefits. There can be no other conclusion drawn from the fact that there were a total of 1816 appeals for diagnosis, and 625,037 for certification of incapacity, than that the compulsory insurance scheme breeds a relationship in which the prevailing emphasis is not the skillful treatment of disease.

It should be explained here that the Epstein law, in its present form, does not provide for sickness insurance benefits. Neither did many of the compulsory sickness insurance plans in Europe, when they were first proposed. It is but a step, and a short one, from collectivist practice of medi-

cine to collectivist indemnity for sickness, which could be expected to follow closely, and the two would soon be identified in operating technique.

Interest aroused by the foregoing figures relative to supervision of panel doctors, induced me to turn to the 15th Annual Report of the British Ministry of Health for 1933-1934. This is a book of some 400 pages. The subject of National Health Insurance forms but a minor part of the report and even so it quotes many conditions and figures of interest to us, particularly in view of the present day agitation for this type of medical care, the more so as they are at considerable variance with those often quoted by the advocates of compulsory sickness insurance in this country.

There were 15,150,000 persons insured under the system and there were 15,500 physicians who did this type of practice. Thus, if each physician had an equal number of patients on his panel, his patients would number 970, and with a remuneration of 9 shillings per patient per year the income would be £437, or 2,185 present day dollars, but as this amount was subject to a 10 per cent emergency deduction, it is reduced to \$1,967. Even this amount was not net, being subject to additional details to be mentioned later, to say nothing of income and other taxes. It must not be forgotten that all panel doctors did not have the same number of patients by any means, thus the majority had an income of less than \$1,967, and the minority received larger sums. This is scarcely compatible with the quoted average of £500 to £600, or \$2500 to \$3000 so often mentioned in sickness insurance statements made in the United States. Let us assume that 20 per cent of the doctors do have an income of £600 or \$3000, what would be left for the remaining 80 per cent? Exactly an average of \$1700.

Let me analyze if you will allow, other figures quoted in the report, which are instructive to us.

The cost of medical care is detailed as follows: The total medical benefit cost was £8,420,000 or \$42,100,000. Of this sum the insurance doctors received £6,077,000 or \$30,385,000 divided as I have stated. The remaining £2,343,000 or \$11,715,000 was allowed as follows: £1,863,080 or \$9,315,400 to the insurance chemists for drugs and appliances, an average of 62 cents per patient per year. Even so there is a strong paragraph in the report on the investigation of excessive prescribing and while the accusations were numerous the convictions were few, but amounts as high as \$100 were deducted from several doctors' incomes as fines.

For medicines supplied by doctors personally on account of mileage to outlying districts, £196,000 or \$980,000 was allowedaveraging about \$128 per panel doctor.

The sum of £63,900 was paid on account of insured persons exercising their option to claim treatment through approved institutions, and £7,250 on account of insured persons who were required or allowed to make their own arrangements for medical care. In other words, a total of \$355,750

was allowed for the purposes stated. Finally £9,000 or \$45,000 was set aside for post-graduate study courses. Of this amount only £2,830, or \$14,150 was used in 1933 for this purpose in grants to 102 doctors. This equals \$139 each. Can you visualize what sort of post-graduate course can be had with board and lodging for this sum? Let us assume for the sake of argument that the whole amount of £9,000 or \$45,000 had been used. This would mean a bit over \$3 per year per panel doctor, and each one could thus be entitled to the large sum of \$15 if each would seek instruction once in 5 years. These figures speak for themselves, and I quote them on account of the rosy description of this feature by the proponents of compulsory sickness insurance in this country.

I hoped as I read the report that the figures quoted would be followed by equally detailed ones concerning administrative costs. The quotations in this regard are rather involved however as they include other "benefits" so that it is impossible to figure the net cost of the sickness insurance from them. The inclusive figures as follows are of interest.

Receipts for 1933 Contributions (Employe,

Employer) nterest and Other Receipts

Parliamentary Votes, Grants

Total Receipts	£31,946,000	\$159,730,000
Extenses Medical Services (Prev. Detailed) Sickness Benefit Disablement Benefit	£8,633,000 9,562,000 5,095,000	\$43,165,000 47,810,000 25,475,000
Maternity Benefit Other Benefits, incl. Sana- toria	1,296,000 2,204,000	6,480,000
Cost of Administration	£26,790,000	\$133,950,000
Approved Societies, Ins. Committees £3.923,000 \$19,615,000 Central Departments		
	4,764,000	23,820,000
Total Expenses	£31,554,000	\$157,770,000

£22,020,000 4,870,000 5,056,000

\$110,100,000

24,350,000

It seems unfortunate for our purpose that administrative costs are not as detailed as those for medical services, but in any event, large sums of money are concerned. What would be the result of such a

system in our country, with all the opportunities it offers to "administrators?"

After all, the matter that concerns us most is the quality of the medical services rendered under such auspices. Much has been said and written in this respect, and I can but repeat that in my experience in England, the insured patient has little regard for his panel doctor and in the event of a serious condition, in his own words he secures a "real doctor" if it takes the last shilling he has.

From 50 per cent to 60 per cent of the patients at the free clinics of London hospitals are insured persons who could have consulted their panel doctors without cost. It is a common experience in these clinics that no actual diagnosis has previously been made by the panel doctor, not because of lack of ability on his part, but on account of the short time he is able to devote to the

insurance portion of his practice.

The following is no uncommon experience in the panel doctor's office in England. Long before the office hour a line of patients may begin to form at the door. It is opened on the stroke of the office hour. Perhaps they go in one by one, or in small groups. Shortly they begin to come out of another door, This is mass medicine. It will not, it cannot, result in an improvement in preventive medicine, which is one of the chief arguments of its proponents. Yet such a claim is made in the report for 1932 of the Chief Medical Officer, who states that the 21 years' experience with the system justifies the original prediction that it would be an important factor in preventive medicine. But the London Times of September 27, 1934, quotes from the last available official figures, and states that among the insured population only, excluding loss due to sickness for which benefits are not payable, there was time lost to industry through sickness in 1933 a total of 29 million weeks' work, or 12 months' work for 558,000 persons. This is the equivalent of 121/2 days per workman per year as compared with 9 days before the compulsory insurance went into effect. Thus there is more sickness instead of less, which should perhaps lead us to call this type of practice sickness "assurance" instead of "insurance." In Germany the loss to industry through sickness has trebled in the 50 years of sickness insurance while in the United States this average loss of time per workman per year is about 61/2 days which is no increase over the figures of 25 years ago.

In support of the statement that sickness insurance does not improve the distribution of preventive medical care, I wish to quote from the Journal of the American Medical

Association for April 13, 1935.

"Diphtheria morbidity and mortality rates seem to offer a fairly sound test of the quality of medical service received by a community. The conquest of diphtheria is now in process. The methods of achieving victory are known. The date of complete triumph depends on the way in which these methods are applied to the entire population. Diphtheria death rates vary directly with the extent to which these known and tested methods of prevention and treatment are made available to the population. This situation furnishes conditions, almost laboratory in type, from which to determine the social value of a medical service.

"The arguments for compulsory sickness insurance may be summed up in the claim that it removes the economic obstacles to the giving of medical service and thereby secures a wider and more effective distribution of that service. Because of the interest in the progress of this conquest of diphtheria, statistics have been gathered through-

out most modern nations.

"The League of Nations has assembled the reported diphtheria cases from 1923 to 1933 for a number of countries.

"Variations in the number of cases between countries or in time within any country bear no relation whatever to the existence of insurance, unless it is a negative relation. The number of cases has increased in Germany and Austria, where the insurance system extends to the family, and also in England and Wales, where families are not included. The number of cases has declined most rapidly in Canada and the United States, where there is no sickness insurance.

"Promptness of treatment with immediate application of recognized remedies determines the mortality. Again it is noted that the rate of decline in mortality is more rapid in the English and Scottish towns, where children are not included in the insurance system, than in Germany, where they are included. But the most striking fact is that in neither of these countries has the decline been as rapid as in the United States, with no insurance. These figures for the United States, however, do not tell the whole story. This country and Canada, unencumbered by insurance, are the only ones in which there seems to be a possibility of complete victory. In 1933 the following eleven cities of considerable size had no diphtheria Duluth, deaths: Elizabeth, Hartford, Rochester, Salt Lake City, Seattle, South Bend, Spokane, Springfield, Syracuse, Yonkers. Some of the very largest cities in the United States had death rates much less than even the low average Some of these and their death rates per hundred thousand in 1933 were as follows: Philadelphia, 0.7; New York, 1.2; Baltimore, 0.7; Chicago, 0.2; Milwaukee, 0.8; Omaha, 0.9; St. Paul, 1.1; Minneapolis, 1.4; Oakland, 0.7; San Francisco, 1.2.

"Judging by these facts, the conclusion seems inevitable that the very classes for which insurance is proposed are now receiving under a system of private medical practice, in the United States and Canada, medical care far superior to that which is supplied when the same classes are put un-

der an insurance system.

"That this conclusion is justified is also the opinion of the observers in countries now having insurance. Edwin H. T. Nash, public health official of England in discussing 'The Present Position of Diphtheria Immunization' in the Journal of State Medicine, September, 1934, pages 522 to 526, says:

says:

"'At long last this country is really waking up to the importance and safety of

immunization against diphtheria.

"'America has been some ten years ahead of us in this matter, due to a certain extent to the American flair for wholesale publicity together with a more polyglot population in its big towns that is more susceptible to flamboyant methods of propaganda than our more sober-minded and less emotional

people. . . .

"'As a contrast compare London, with I per cent of its school population immunized, with New York State, where the numbers immunized exceed 700,000. We

numbers immunized exceed 700,000. We have no figures in this country that can compare with those on the other side of the Atlantic. None of us who are immunizing on a larger scale here can approach the figures in some of the American towns where diphtheria is being steadily eliminated. Take Hamilton, Ontario.

"'In 1922 there were 32 deaths from diphtheria, when immunizing was begun.

"'In 1925 the deaths had dropped to 14; in 1929 to 1; in 1930 there were 2, and in

1931 there were none at all. . . .

"Just as I finish writing this paper, the Medical Officer of the 12th May reports that "The diphtheria ward of the Alexandra Hospital at Montreal has been closed because there are not enough cases to warrant it being kept open." It was in 1928 that immunization against diphtheria was started in Montreal. The death rate that year was 28 per 100,000. In 1929 it fell to 15, in 1930 to 10, in 1931 to 6, and in 1933 to 2. Last year 52,063 Montreal children were immunized."

It is not easy to understand how altruistic laymen can see in compulsory sickness

insurance the glorious vision of every man, woman and child getting adequate medical care. Nobody knows better than the physician what a very large order this is. Certainly it is not to be achieved by a system of compulsory insurance which has the result, everywhere that it has been tried, of over-taxing the physician, so that he cannot take the time to do his work well.

The healing art is a difficult one, even when practiced by men of years of experience, with unlimited time at their disposal to pay attention to those cases presenting difficulties. It cannot be hurried and be effectual. Each case is an individual problem, For example: a middle-aged man consults his physician. He doesn't feel very well. The doctor asks him whether he has difficulty in climbing stairs. Now this patient may be in the very early stages of heart impairment, yet he is likely to resist questioning by his doctor which might disclose a disability. His pride intervenes. He is "Just as good as he used to be." He denies he has any difficulty climbing stairs, not realizing that by withholding from his doctor important information he may be shortening his life. But it is the doctor's obligation to find out. He has ways to help him, such as testing blood pressure, and the electrocardiograph. These serve as aids in appraising the condition of the heart and vascular system. The doctor knows very well that there may be a slight impairment at middle age which, if discovered in time, will respond to treatment and a more carefully regulated life. Under sickness insurance, he is not likely to have the time to devote to this man to get from him those casual admissions which every doctor knows are reluctantly drawn from many patients' lips, but do fall, ultimately, if he is persistent, tactful, and gains the complete confidence and good will of the patient. The fact is, and laymen need to be told this again and again, that the patient's conscious or unconscious resistance to the doctor is frequently an impediment to giving him medical care. Time is required to overcome the patient's own unintentionally obstructive conduct. "What is spoken of as a clinical picture," says Dr. Francis W. Peabody, Professor of Medicine, at Harvard Medical School, "is not just a photograph of a man sick in bed; it is an impressionistic painting of the patient surrounded by his home, his work, his relations, his joys, sorrows, hopes and fears."

In no country where compulsory sickness insurance exists, is a physician able to give enough time to each patient to render the best service of which he is capable. There is plenty of evidence to support this state-

ment, which may be said to be self evident from the fact that panel doctors everywhere are called upon to treat 30 to 60 cases per day. I have talked with many persons from European countries whose statements substantiate my personal observation in England. I wish to call as witnesses a few persons who are selected because of some recent connection with the public discussion of the subject.

Gustav Hartz of Berlin will speak for Germany. He wrote an article entitled "Will America Copy Germany's Mistakes?" which appeared in the New York State Journal of Medicine for March, 1935. I wish to quote a few comments which Mr. Hartz makes on compulsory sickness insurance in Germany, which has been in opera-

tion in that country for 50 years.

"The insured workman becomes a second class patient. The mass demand compels a limitation in the use of medicines. Doctors must not prescribe what they consider good for the patient, they are only allowed to give remedies entered in a book of medical regulations for insurance purposes.

"Medical science has become a cheap article and doctors have given up conscientious treatment. The genuine patient is neglected, is not given the necessary care. The greater the mass consultation, the lower are the doctor's fees. They are, therefore, com-

pelled to resort to mass practice.

"All this is at the workman's expense, for the part of the premiums supposed to be paid by the employer is in reality borne by the workman either as a consumer or wage earner. As the employer's premium share is immediately connected with the wage, it is shifted over on the wage. In Germany, no one any longer doubts the fact that the employer's share of the premium is taken from the workman's wages. What the employer pays as his contribution, he cannot pay the workman in the form of wages.

"A network of deception has been spread. In millions of cases wrong was turned into right and the gates opened wide to fraud. When wages are being decreased, when work is scarce and work hours shortened, when there are fewer shifts, many holidays, sick insurance comes in handy. One objects to the work he is given, another does not feel like working. Matters soon make an extensive controlling system necessary. This ends in badgering all persons.

"Patients are visited in their homes by controlling officials who have to convince themselves that the patient is really ill and not doing any work. The sick insurance engages so-called confidential doctors who have to submit the patient to a final examination to see whether he is too ill to work

The results of such examinations are to a great extent startling. Here is one instance from among thousands: 2008 patients were ordered to appear for a final examination. Eight hundred sixteen of them at once declared their complete recovery; 289 were found to be well by the confidential doctor. So nearly half of them were not ill at all.

"The confidential doctor is, so to say, the medical policeman, who not only controls the patients but also his fellow doctors who

are treating them.

"The genuine patient is justly indignant to find that the existence of his illness is doubted, and that he who has always paid his premiums regularly and has a right to demand conscientious attendance is considered a cheat.

"This system, together with the rest of the bureaucratic apparatus, has wedged itself between doctor and patient, completely destroying the patient's confidence in his physician, which greatly retards all recovery."

Shortly after the publication of the Hartz article, a corroborating letter was received from a German physician at present in this

The writer was Dr. Paul G. Frank, a resident of Kew Gardens, New York. Said Dr. Frank:

"For almost thirty years I have worked as a German panel doctor under the conditions of compulsory sickness insurance, and for many years I was a member of the physicians' committee.

"During this period I witnessed a deterioration of the medical profession. It was gradual. It came about by the removal of the sanctions of preferment by skill and the substitution of preferment by convenience. What I mean is that an insurance scheme soon becomes a business—it must do so to succeed, while the practice of medicine must be a profession to succeed at its best, and the two will not mix. In Germany the physician who was most adaptable to the advancement of the plans of the insurance officials, and who most pleased the patient for reasons perhaps quite other than skill. obtained the most rapid preferment. It is true there were a few opportunities left which made it possible to adhere to higher standards—I for instance had such an opportunity being a specialist—but many men who might have gone far were ruined by the stultifying panel practice.

"In the late nineties at the university we did not much esteem the panel idea. In those early years of compulsory insurance the lay public knew these doctors to be second-rate. Some years later when I left the university clinic I ceased to laugh at the panel doctor,

for I became one myself. My fee averaged 50 cents each for medical cases of three months' duration! Figure out for yourself how many of these I had to have to live decently, and figure, also, how much time I could give to each case. Of course, it goes without saying that a young man of high professional ideals does not think first of money, but first of his duty to his patient; yet he is forced, under sickness insurance, to make a decision between these two motives which often disastrously affects his attitude toward his work. It is only too easy to weaken, for he must live. The trouble with the scheme is that it encourages careless work by making it more easily profitable; the individual practice encourages good work, by making it, in the long run, more profitable.

"I dislike to touch upon the fact that the quality of young men choosing medicine as a career has not improved under sickness insurance, yet I believe it to be true. Bismarck hoped to combat socialism by such insurance, but on the contrary, it worked to encourage socialism. As a result there has been built up a bureaucracy which governs the whole system, and its members have been drawn from the laboring, clerical and generally less educated classes. More and more as the years go by the young students of medicine come from families of perfectly respectable, but not superior intellectual and emotional background. Response to professional traditions calls for certain native attributes which are not always acquired through university training alone, yet are of great social value in those who are to practice the difficult and dangerous art of healing.

"The American people will do well to pause long before adopting compulsory sickness insurance, remembering that such a system once instituted is sure to perpetuate itself. I have been in this country a year and a half. Some of the hospitals here are the most wonderful I have seen anywhere in the world, and I have travelled extensively in Europe. I wonder whether the average quality of medical care given in the United States is not superior to that which is given in countries where insurance

plans are in operation.

"May I close by quoting a line from Shakespeare, which seems pertinent: 'Seeking to better, oft we mar what's well."

Turning now to Austria, let us summon a witness who appeared before the Legislative Committee of the Medical Society of the State of New York when it was in session at Albany in January, 1935. He is Dr. Jacob L. Moreno of New York City, director of research, New York State Training School for Girls, Hudson, New York, and adviser of the Subsistence Homestead Division, Department of the Interior, Wash-

ington, D. C. Said Dr. Moreno:

"I know from experience with the actual reality that no matter how perfect the picture of ideal care for the poor that is presented by such schemes for sickness insurance, in practice they do not work. They cannot work, because they fail to take account of factors in human relations which are indispensable to the practice of the healing art.

"No physician is capable of properly treating the large number of patients sent him under sickness insurance. He is forced to evolve some mass production plan of operating his office to run people through his mill as fast as possible. A quick look, a stock prescription, a pat on the back, and

out the door...

"The 'rush' system of handling patients inevitable. When the technique of getting them in and out fast enough is perfected, the doctor begins to lose that intangible 'something' which is vital to both himself and his patient,—his morale, I do not know any doctor who remained long at this sort of practice in Austria who did not become hardened. A doctor's personal interest in his patient is essential. The response he makes emotionally to the trust reposed in him is important. If the patient comes to the doctor because of confidence in him and not merely because he is an insurance doctor, interest and insight are quickened.

"Every person's capacity to expand emotionally, and to sustain a confidential relationship, is limited. A physician may be able to maintain a keen mental activity while exemining a few cases a day, but after his limit is reached, the power to sustain the faculties on a high plane wanes, until, finally, when the last case of a long line is reached, the patient becomes merely a serial number on a piece of paper. Insurance forces on the doctor an utterly impossible human task—to sustain a genuine personal interest in all the individuals of a miscel-

laneous crowd at his door.

"The insurance doctor does the best he can, but patients suspect they would get better attention if they came to him during his private office hours when he could give them more time. This is a distinct and definite injury to the character of the physician. He must hurry through his insurance patients so that he can have plenty of his best self left to take care of his private patients. This is a corrupting influence. He knows he has not lived up to the highest tenets of his profession to give his best to every patient who comes to him. He has

been forced by circumstances created by law to do less than his best toward some of his patients, and even his best with the few who see him privately ultimately becomes

not so good as it was once.

"Nobody who has not seen such schemes in practice as I have, can realize how odious they are. They destroy everything that makes the healing art effective. A new face comes between the doctor and the patient, that of an inspector or supervising physician, or an insurance bureau bookkeeper, questioning this and that particular, without the intimate understanding derived from having seen and known the patient. At best, the real patient, the one for whom the mass production doctor is working, whom he must please if he is to live, is not the sick man, but an adding machine in the office of a bureaucrat who pays the fees out of an insurance fund. This man doesn't care whether the patient lives or dies, only how much he costs the fund. And his influence is exerted only in the direction of economy and other externals.

"Supervisors are needed in sickness insurance organizations. A good controller or supervisor who brings in many complaints against doctors is considered a good supervisor—he is headed for promotion because medical practice has now become a business instead of a profession. Thus do we destroy a truly healing relationship in which trust and confidence is the basis, and substitute a chain-store cut-rate imitation, which corrodes curative values needed to heal the

sick

"The system which we now have in the United States is not perfect. But I know from personal experience that the condi-tions imposed by compulsory sickness insurance are far worse. Insurance is a type of socialized medicine. It is impossible to socialize the doctor unless the business man, the banker, and the lawyer are socialized, too. Until the time comes, if it ever does come, when we have communism or some form of collectivism, compulsory sickness insurance simply will not work. Though it applies only to the lower income groups, those groups will always feel they are getting less than they ought to get, even if the doctors are men of quality having lucrative private practices in addition to their insurance practice. Like all half-way measures, it will fail, despite the well-meaning altruism of those who sponsor such legislation. They do not realize, as the physician does, who has practiced under such a system, how destructive it is to quality in medical care.

It is such a system as this which is proposed for the United States! Can the reader

. ...

now appreciate why the medical profession in this country feels that in opposing it, they are fighting for their very existence as an honorable profession? We are asked to occupy our lives with false gestures of administering good medical care which the conditions will not allow us to give; we are asked to make ourselves a part of a gigantic bureauracy and play politics with human lives.

What then, is the answer to the problem of improving the health of the public? I have alluded to it briefly in the first part of this discussion; I should like to refer to it again now. Health education is the only sound measure. That portion of the public which is either ignorant or indifferent, need to know, and act on the knowledge that they must be examined by a physician, to learn their true condition; that they cannot tell it themselves, that they cannot rely on mere absence of pain as proof they are perfectly well. To teach people that they should have medical care when they are well and not wait until they are sick is an educational problem, and sickness insurance cannot possibly affect this element in the population. So far as any need for better facilities to care for catastrophic illness or acute diseases, there is no evidence that these emergencies are not adequately met in the free clinic, the free hospital, and the private physician's practice.

The medical profession does not quarrel with the social theorist who wishes to bring preventive medical care to more people than now get it. That many lack this care always has been true, and it is true in every country today where sickness insurance is practiced. The school physician finds many children who have defects of tonsils, adenoids, sight; many who are crippled; cardiacs. The world war disclosed fully that much medical care could be given the average citizen to his advantage, but it also disclosed a degree of indifference to their own condition, which was the basic reason for the continued existence of many of these defects. Are there fewer defects under sickness insurance in England, Germany or Austria? I know of no such figures. But I do know that America, under individualized medical practice, has a lower sickness rate than these countries, and that preventive medicine, so far as I can find any statistics, has gone farther here, especially in diphtheria inoculation, in which we far outstrip countries which have succumbed to the illusive dream of collective medical practice.

If there were a doctor on every street corner, and medical service were offered free of charge, a large multitude of people would not stop to get it. They would continue with their physical defects for any one of a dozen reasons, and every doctor knows what they are. There is refusal point blank to believe these matters to be important; there is lack of intelligence to understand explanations when made; there is plain indifference, and rebellious disbelief in "high brow" ideas. These are problems for the educator. People of this class are not yet ready for preventive medicine; they think they do not need the doctor until they fall ill. Then, as we have indicated, they can and do obtain medical service.

Are we quite prepared to desert individualism in medicine in favor of collectivism, or any of the various forms of the socialistic state? Let us consider this theme, because it is apparent that this is the fundamental issue implicit in compulsory sickness insurance.

It is chiefly since the world war but also to some extent before then that socialism or at least socialistic trends have become increasingly apparent not only abroad but at home. The early history of the world relates the gradual establishment of increasingly stringent fundamental customs which may be considered evidence of collectivism in the broad sense. The Renaissance period of the fourteenth century was the rebirth of individualism, when men again became conscious of their individual power, exercised it to a new degree and realized personal responsibility. The Reformation of a later day was but a manifestation of this individualism.

It was not until early in the eighteenth century that rationalism, as we know it, became at all firmly established and it took all of another 100 years or more to create a "rugged individualism" by the complete breakdown of the old fundamental customs as the result of broader and higher education, the wonderful developments of science, the mingling of commercial and scientific peoples and the international competition in industry.

The era of "rugged individualism" which followed, noted the most brilliant period of progress in every art and in every science. So much so is this the case that one easily reaches the firm conviction that true progress is due to individual rather than to collective effort. This is the period in which America rose to its pinnacle of success, and in retrospect of this rise we can all point to individuals and not to groups who are responsible for it. Our country had its origin from those seeking individual freedom, its constitution is based on this same principle, its greatest success resulted from the achievements of individuals and its glory will go down in history as created by

this "rugged individualism" rather than by group or collective effort in any sense.

In recent years, however, we have evidence of retrogression in the increasing domination of group spirit, the sacrificing of individual independence, a lessening sense of personal responsibility and a growing paternalism; the former intrepid pioneer in thought and act leaning more and more on the soft bosom of the state. Russia failed in her attempt in 1905 but succeeded in 1917, Italy followed in 1922, Germany after a trial as a republic for a decade or more has now also succumbed, and present day policies in our own country may throw us into the same class of nations yielding individualism to group domination and control.

The socialization of medicine is but a manifesation of the same spirit. The argument in its favor and those in opposition have been the subject of heated debate in recent years; they cover many pages of print which have been read and reread by us all sufficiently often to justify one opinion. At the moment the medical profession is concerned with fundamental principles; we are fighting to prevent collectivism from succeeding individualism. We wish to avoid the inevitable retrogression which according to all history results when group control supplants independent individual effort.

It is hoped that nothing which I have presented here will be taken to mean that it is not desirable to promote action to improve the medical care received by persons in the lower income group, or to provide methods to distribute the cost of this care. My contention here is that compulsory sickness insurance will not achieve either of these objects. The American Medical Association has made studies of many plans which have been tried in various communities, and its bureau of medical eco-

nomics presented a special report on this subject at the annual meeting held in May, 1935. This organization, as well as many state societies, including that for New York state, have approved plans for voluntary insurance, in which the vices inherent in the compulsory type are not to be found. These plans are not germane to this discussion, but I cannot dismiss the subject without adverting to them, to apprise the reader that the medical profession is interested in assisting the establishment of sound economic projects for the wider distribution of medical care. None of these plans is a panacea. Some of them will work in certain communities, but must be altered to fit the institutions of other communities. There is no "royal road." The path to improvement

is long and arduous. Many physicians feel poignantly that an injustice is done us when, by implication and direct statement, the public is asked to believe that the doctors of the nation as "merchants of medicine" are obstructing, for purely selfish reasons, a movement to provide adequate medical care for the masses. Let me ask if it is reasonable to suppose that a group of men with so long and consistent a record of devotion to the task of alleviating the sufferings of mankind are blithely to be outdone in effective humanitarianism, by members of certain pressure groups most of whom would not know how to pull a mote out of an eye? In making plausible theories we may be easily surpassed, for we are without skill in this; our claims for a sound and disinterested judgment rest with the very acts of performance on which society must depend for any improvement,

With the feeling that it is neither necesary nor desirable to distrust the competent man, nor to impugn his motives, this discussion is submitted for the thoughtful consideration of the public.

ANNIVERSARY DISCOURSE

Aspects of a Philosophy of Government in a Sick World

bу

WALTER LIPPMANN

When Dr. Hartwell and Dr. Pool invited me to speak here this evening, they suggested that I might talk upon some aspects of the relation between the medical profession and the community. They supplied me with a collection of pamphlets and reports and reprinted addresses dealing with medi-

cine in its public relations. I read them diligently. But the more I thought about the questions at issue, the more uneasy I became. For I realized that I did not really understand them and that all I could hope to do was to enlighten you about the extent of my own ignorance. At this point I began

The Eighty-niuth Anniversary Discourse delivered before the New York Academy of Medicine, December 19, 1935. Reprinted by permission from the Bulletin of the New York Academy of Medicine (December, 1935).

to wonder wistfully whether the Ethiopian war might not require my presence in London or Geneva or Addis Ababa tonight; for this seemed a not wholly unconvincing way of letting the Academy of Medicine solve its problems without my assistance.

I am making this confession of embarrassment and cowardice because it enables me to boast about my sudden discovery of a triumphant solution of this predicament. If I were a politician, I said to myself, I should, of course, have to act as if I knew the answer to every problem: what politician has ever admitted that he did not know the answers to anything? Perhaps if I were a commentator on current affairs I could not escape expressing an opinion even if I were not entitled to an opinion. But surely, I thought, in a gathering of medical men it will be easy to say candidly that there are aches and ills which flesh is heir to that even the best physician does not understand and cannot cure. After that I felt at ease. It is a great relief to come from the world of public affairs, where no one dares to admit that he does not know, where no one ever admits that he has made a mistake, where no one ever admits that he is puzzled, into a world where it is respectable and honorable and safe to put aside the pretension of infallibility and of omniscience.

I should like to discuss an aspect of the philosophy of government in a disordered world. Philosophy is perhaps too pretentious a name: what I have in mind is an attitude towards government which, when it becomes articulate and explicit, may be

dignified as a philosophy.

In the realm of government, whether a man is simply an interested citizen or an active politician, or a responsible official, or a student and thinker, the subject matter is complex, it transcends his personal observation and experience, it comprises an extraordinarily large number of intricately related variable elements. In order to think about politics at all, in order to make public affairs comprehensible to the human mind, men have to create for themselves some kind of mental image, some sort of model, some hypothetical pattern which is simpler and more familiar than the reality which William James used to call the buzzing, blooming confusion of the actual world. It is beyond the power of ordinary minds-I am tempted to say that it is beyond the power of any mind-to deal continually and effectively with the data of experience in all their raw, heterogeneous fullness.

At different times in the course of history men have used different images to represent to themselves the social order in which they live. One of the oldest and most persistent of these images is derived from the patriarchal family; the relation between the ruler and his subjects is conceived as similar to that between the patriarch and his children. Then there is the image derived from war: the ruler's relation to his subjects is conceived as the relation between the chieftain and his warriors. This, incidentally, is a social image which has recently had a spectacular recurrence in the fascist states of Europe. Again and again, from the time of the Graeco-Roman thinkers, men have at certain times conceived society as a body politic in which each class, each rank, was an essential member. Usually the current image has been an imitative reflection of the accepted or dominant science of the age. Thus in the Eighteenth Century, the profound impression made upon men by the Newtonian conception of the physical world was carried over into politics, and men conceived society as a system of forces. Our own constitutional system was devised by men who had the daring to conceive a federal republic in which the states would remain as distinct as the separate planets and as unified as the solar system. In the Nineteenth Century, the Darwinian imagery took possession of many political thinkers: economic competition and the imperialist competition of national states were regarded as illustrations of the struggle for existence of a surplus population in an insufficient environment and of the survival of those most fitted to survive.

Now in our own day a different image has taken possession of many influential minds. Let us call it the image of the statesman as engineer. It is not hard to account for its popularity and persuasiveness. The most obvious triumphs of modern man, those which are most easily appreciated, are his great buildings, his great ships, his great machines, his great tunnels, dams, canals. Mankind has been profoundly impressed with the contrast between the efficiency of these engineering works as compared with the inefficiency of statesmen, of financiers, and of business men. The engineer, it seems, is able to achieve what he sets out to achieve. He can plan and he can carry out his plan. He knows what he is doing and he does it.

So the idea took hold that society might be run by engineers, might be deliberately constructed according to a plan and then operated as efficiently as a great machine. When I was a young man, Mr. H. G. Wells was the prophet of this vision, and there were few in my generation who were not spellbound by the idea that if only we could get rid of politicians and of competitive

business men and turn society over to the engineers, a clean, orderly, efficient and gra-cious civilization would be brought into This vision, if you will remember, played an immense part in the early enthusiasm for Mr. Hoover, Around 1920 he was hailed by many of us as the ideal ruler of men because he was not a politician but an engineer, though today, such is the changeableness of men, he is criticized precisely because he is not a politician. In the postwar era the image of the engineer seems to have taken hold not only of the best minds of the Republican Party in America but of the best minds of the Communist Party in Russia. One of the chief reasons why Soviet Russia has exerted such attraction upon so many men is that the planned economy of Russia seemed to be an example, the first in history, of the application of engineering principles to human society. There were several years, I should say roughly from the crash of 1929 to the end of 1933, from the breakdown of prosperity to the beginning of recovery, when the ideal of an engineered and planned economy had almost completely captured the imagination of the Western World. Everyone who raised his voice talked about planning something, the Chamber of Commerce, the heads of hig corporations as well as the New Dealers and the Progressives. No doubt they had different ideas of how to plan and what to plan for, but the underlying image dominated most minds. The notion finally reached its grand climax, and its reductio ad absurdum, in the vogue of technocracy.

The point I wish to make is that the conception of government as a problem in engineering is a false and misteading conception, that the image of the engineer is not a true image of a statesman, and that society cannot be planned and engineered as if it were a building, a machine, or a ship. The reason why the engineering image is a bad image in politics, is a bad working model for political thought, is a bad pattern to have in mind when dealing with political issues is a very simple one. The engineer deals with inanimate materials. The states-

man deals with the hehavior of persons. A mode of thought appropriate to the organization of inanimate elements cannot be applied successfully to the organization of animate ones. It is as radical a misconception as would be the attempt to become an architect by studying music or a horticulturist by studying astronomy. The engineer who plans a building can calculate the weight which his steel will sustain. But he does not have to consider whether his girders and his bricks will renew their vitality from day to day and reproduce their

kind from generation to generation. Nor does he have to consider whether they will be willing to hang together in the structure into which he has put them, whether the girders, for example, will grow weary of supporting the bricks, and begin to have purposes which he did not assign to them

when he made his plan. Surely it is almost self-evident that if, as an instrument of political thinking, we must have a working image derived from some more familiar discipline, then it is to the biological sciences that we must look for an analogy. Since the statesman deals with living things, he had better take his analogies and his inspiration from those who deal with living things, from farmers, and animal trainers, and teachers, and physicians rather than from astronomers, and engineers and architects. For analogies, images, working hypotheses, patterns, whateyer you choose to call them, which come from man's dealings with the world of living organisms will at least have the virtue of keeping vividly in his mind a sense of what he is handling. Governing is an art, It requires, as all arts do, a sense of touch, an intuitive feeling for the material, a kind

of sixth sense of how it will behave. The masters of any profession know something more than it is possible to communicate; they are so sympathetically at one with their subject that instinctively they possess the nature of it. Before they have reasoned consciously, they have smelt, have felt, have perceived what it is and what to do. It used to be said that you did not have to be in the ring with Jack Dempsey for fifteen rounds in order to learn that he was a champion. Likewise, the master of a subject, whether he is a carpenter or the rider of a horse, a diagnostician or a surgeon, will quickly disclose in the inevitable emergencies of any human activity whether he possesses that intimate feeling, that flair, that uncalculated aptitude which distinguishes the first rater from the second-

Now among public affairs as elsewhere, since everything cannot be reasoned out a priori in each emergency, it is of the utmost importance that the political tradition of a country should predispose men towards a true and reliable sense of how living men in a living society behave. That is why the dominant imagery is so important.

The image of a planned and engineered society has the effect, I believe, of destroying the intuitive feeling for what society actually is and of the sense of touch in dealing with human affairs. The grosser consequences of it are evident enough: in the supreme impertinence with which com-

munist and fascist states treat human beings as if they were animate materials to be fabricated by the dictators; in the ruthlessness with which they cut human nature to the shape they desire and nail together in designs of their own the living spirits of men. This notion that society can be engineered, planned, fabricated as if men were inanimate materials becomes in its extremist a monstrous blasphemy manifestations against life itself. It can also take milder forms which merely produce temporary confusion and inconvenience as in the fantastic attempts, now happily concluded, to write in three or four months some five hundred codes for the detailed conduct of all business throughout continental America.

The man who approaches public life with a feeling for living organisms will not fall into the illusion of thinking he can plan or fabricate or engineer a human society. He will have the more modest aim of defending it against the invasion of its enemies and of assisting it to maintain its own balance.

Remembering that a society is an association of living persons, and not an arrangement of inanimate materials, he will never imagine that he can impose upon those living persons and their descendants his private preferences. He will recognize that the function of government is not to decide how men shall live, what kind of men they shall be, what they shall spend their energies upon. Government cannot direct the life of a society. Government cannot shape the destiny of the human race.

There are some who think that government should use all its powers of coercion to make the social order correspond with their own ideal of a nobler and more satisfying social order. But this is as if a doctor dealt with a patient on the assumption that he must use drastic medicine if he finds that his patient is not as strong as Hercules, as beautiful as Apollo, and as wise as Zeus. He would be an absurd doctor. The sound physician, I take it, is not attempting to make a superman out of his patient. He takes measures to protect him against the invasion of hostile bodies. He cultivates habits which improve his resistance. He intervenes with medicines and surgery when he thinks he can assist the patient in recovering his own equilibrium.

Nearly 250 medical men heard Dr. Francis G. Blake, professor of medicine at Yale University, discuss diagnosis and special treatment of respiratory diseases at the monthly meeting of the Williamsburgh Medical Society in the Jewish Hospital, 555 Prospect Place, on Dec. 9.

Always, if I understand the faith of the physician, he regards himself not as the creator, designer and dictator of the nature of man but as the servant and the ally of nature. There are times to be sure when his patient is prostrate and the doctor must be the master of his whole regime. But even in these times, the good doctor will be continually seeking for ways, not to make a new man of his patient but to encourage those recuperative powers which may at last enable the patient to walk again on his own feet.

There is a vast difference between those who, as engineers dealing with inanimate materials, can dictate to nature and those who, as physicians dealing with living organisms, must respect nature and assist her. My thesis is that statesmen had better think of themselves as physicians who assist society than as engineers who plan and fabricate it. They will understand these problems better if they realize that society has not been invented or constructed by any man or any set of men but is in fact the result of the infinitely complex adaptations by innumerable persons through countless generations. Its destiny is beyond the power of the human mind to imagine it. Its reality is complex beyond the mind's power to grasp it. Its energies are beyond the power of any men to direct it. Society can be defended. Its adjustments can be facilitated. Its various purposes can be clarified, enlightened, and accommodated. Its aches and pains can in some measure be relieved. But society is not and never will be a machine that can be designed, can be assembled, can be operated by those who happen to sit in the seats of authority.

To know this, to realize the ultimate limitations of government, and to abide by them, is to have that necessary humility which, though for the moment it is at a discount in many parts of the globe, is nevertheless the beginning of wisdom. Without it men will use political power for ends that government cannot realize, and in the vanity of their delusions fall into all manner of cruelty, disorder, and waste. They will have forgotten to respect the nature of living things, and in their ambition to be as gods among men they will affront the living god. They will not have learned that those who would be more than human end by being less than human.

The society elected as officers: Dr. Leo Loewe, president; Dr. H. M. Mandelbaum, first vice president; Dr. I. E. Siris, second vice president; Dr. J. F. Morris, treasurer; Dr. C. Goldman, associate treasurer, and Dr. B. B. Berkowitz, secretary.

Society Activities

Committee on Prize Essays

The Merrit II. Cash Prize and the Lucien Howe Prize will be open for competition at the next Annual Meeting of the Medical Society of the State of New York, April

27, 1936.

The Lucien Howe Prize, of one hundred dollars, will be presented for the best original contribution on some branch of surgery, preferably Ophthalmology. The author need not be a member of the Medical Society of the State of New York.

The Merrit II. Cash Prize, of one hundred dollars, will be given to the author of the best original essay on some medical or

surgical subject.

Competition is limited to the members of the Medical Society of the State of New York, who at the time of the competition are residents of New York State.

The following conditions must be observed:

Essays shall be typewritten or printed and the only means of identification of the author shall be a motto or other device. The essay shall be accompanied by a scaled envelope having on the outside the same motto or device and containing the name and address of the writer.

If the Committee considers that no essay or contribution is worthy of the prize, it will not

e awarde

All essays must be presented not later than April 1, 1936, and sent to the Chairman of the Committee on Prize Essays of the Medical Society of the State of New York, 2 East 103rd Street, New York City.

JAMES ALEXANDER MILLER, M.D., Chairman

Medical News

Erie County

Dr. Grover Pemberthy, of Detroit, will address the surgery section of the Buffalo Academy of Medicine on "Tannic Acid Treatment of Burns" on January 8; and on January 15 Dr. C. R. Austrian, of Baltimore, will speak to the medical section on "Differential Diagnosis of Pulmonary Diseases."

New York County

THE "DANGER OF OVERESTIMATING mental ills as a cause of juvenile delinquency" is stressed in a report to the Domestic Relations Court in New York City by a committee of the New York Academy of Medicine which was asked to investigate the medical and mental disease clinics of the court and advise how they could be improved.

The problem facing the Domestic Relations Court is much more than a purely medical one," said the report. "In dealing with this problem, the field of psychiatry has an important contribution to make, but it does not offer the complete solution. The situation calls for cooperation between all the various social, legal, educational and medical agencies available to remedy the conditions which are chiefly responsible for the startling increase of crime in recent years." The doctors assert that "it is not even desirable to provide a complete psychiatric examination for every client," but rather to intensity social case work. "A great majority of the cases are those which a well trained social worker should be able to handle or which an adequately super-

vised probation officer would be able to understand and adjust."

Steuben County

Dr. H. E. Auringer of Addison, was elected president of the Steuben County Medical Society at its annual meeting on November 14 at the Hotel Wagner, Bath. Dr. Auringer served during the past year as vice-president of the County Society and now succeeds Dr. E. P. Smith of Cohocton as president. Dr. C. M. Lapp of Corning was elected vice-president and Dr. R. J. Shafer of Corning secretary-treasurer. Following a luncheon the main address was given by Dr. Albert Kaiser of Rochester on: "Indications for Tonsillectomy." The Society's next meeting, the second Thursday in March, will be held in Corning.

Westchester County

DR. THEODORE WEST of Port Chester was elected president of the Westchester County Medical Society at its annual meeting at White Plains on November 19. Other officers chosen were: Dr. Morley T. Smith of New Rochelle, vice-president; Dr. Erich H. Restin of Mount Vernon, second vice-president; Dr. Merwin E. Marsland, of Mamaroneck. secretary; Dr. Harry Klapper of White Plains, treasurer. Papers of great interest on medical economics were read by Dr. R. G. Leland, Director of the Bureau of Medical Economics of the A.M.A., and by Dr. F. E. Elliott, Chairman of the Committee on Medical Economics of the State Society.

Across the Desk

The Great Carrel Dry Storage Idea

ALLURING POSSIBILITIES intrigue the imagination as the mind plays over the picture conjured up by Dr. Alexis Carrel in his lecture at the New York Academy of Medicine the other evening on "The Mystery of Death." What he was really talking about was how to cheat death, which of course is what the doctors are trying to do all the time. One way he suggests to do it, not yet practicable for humans, however, would be to put the subject into a state of suspended animation. "Some individuals," he remarked, "could be put into storage for long periods of time, brought back to normal existence for other periods, and permitted in this manner to live for several centuries." He did not say he had anybody particularly in mind to be put into storage, but no doubt he could supply a few names, and we could all help with a few more, and it would really take no time at all to fix up a list that would go through with a whoop if put to a vote.

The storage could last "for long periods of time," suggests Dr. Carrel. That is the fine thing about it. The longer the better. The subject could have one of the hotel _placards hung around his neck: "Do Not Disturb." In this simple manner we could wish all our public pests of today on the next generation. What a panacea. We can easily imagine some Nosey Parker of a scientist poking around in the storage warehouse a century hence and exclaiming, "There is a perfectly grand looking man, let's wake him up." Only to say firmly after a few weeks of having him around, "Back to storage you go!" Only the subject's waking days would count as his lifetime, and Dr. Carrel thinks that in this way the storagec might "live for several centuries." A practically perpetual joke on every generation unwise enough to rouse him from his dreams.

NEW MUMMY SONG—"How DRY I AM!"

Dr. Carrel even suggests how the thing is to be done. The subject would be dessicated, or, in plain English, dried. "It is known," he said, "that certain animals such as the small arthopod, tardigradum, stop their metabolism when they are dried. A condition of latent life is thus induced. If, after a lapse of several weeks, one moistens these dessicated animals, they revive and are capable of leading a normal life again." Hope for the scheme is even seen in the report that "the tail of a rat, after being dried, has been transplanted with success to another rat."

What we would say, then, to the bore, or the pest would simply be, "Dry up!" In some climates he would be put in the oven, in our glorious regions of sunshine he could be hung out on the fence. Clearly, however, some authority would have to be set up to decide who should be dried and who not. But that would be easy. Germany now has courts to say who shall be sterilized, and has medical committees to permit or deny abortion. Our newspapers are filled with suggestions that courts or commissions might sanction euthanasia. Why not have the same body pass on requests to dry up, say, Public Pest No. 1? This might just as well be decided now as to wait till the scientists perfect the process. It may not be long now. "We should remember," says Dr. Carrel, "the utopias of today are the realities of tomorrow."

It is inspiring, anyway, to think of the great storage warehouses filled with those better there than here. But like every Utopia, it has its disquieting thought: Moisture would bring them back to life. What if the roofs should leak?

"The Hell of Staying Home"

"THE HELL OF WAR" used to be a favorite title for pacifist sermons. Which led a railroad man to write an article on "The Hell of Railroading," because so many operatives were killed or injured. "The Hell of Motoring" came next, with 30,000 to 35,000 killed on the highways every year, and countless thousands maimed and disabled. But who would have expected a chapter on "The Hell of Staying Home"? Figures just out estimate that 34,500 persons were killed in home accidents in 1934. The National Safety Council estimate that more than 150,000 persons were permanently disabled in home accidents and 5,000,000 temporarily disabled. These accidents included falls, burns, explosions, cuts, asphyxiation, poisoning, and electrical shocks. To meet this situation the Council has published an attractive booklet titled "Safe at Home," telling how to discover and eliminate existing dangers, and what to do in case of fire, asphyxiation, and other accidents. Copies may be had without charge, till the supply is exhausted, from the State Health Department at Albany.

We require automobile drivers to pass examinations and take out licenses before they go out on the road. Why not make people take out licenses before they engage in such a perilous business as staying home?

Books

REVIEWED

Diseases of the Rectum and Colon and Their Surgical Treatment. By J. P. Lock-hart-Munmery, F.R.C.S. Eng. Second edition. Octavo of 605 pages, illustrated. Baltimore, Williams & Wilkins Company, 1934. Cloth, \$10.00.

Among the chapters omitted in the second edition are those on the physiology, and the bacteriology of the large bowel, and among the subjects omitted are intussusception, chronic mucous colitis, and sacral anesthesia. Two new chapters have been added, one on precancerous conditions and

one on acute intestinal obstruction.

The author is very fair and open minded in stating his changed opinion regarding the place of radium in the treatment of malignant diseases of the rectum and anus. In the 1923 edition he states: "So far no single instance of an undoubted cure of rectal cancer by the use of radium has been brought before the medical profession. After considerable experience, I personally advise that it should not be used in the treatment of growths of the bowel, with the possible exception of epithelioms of the anus."

In the 1934 edition he writes: "There is no doubt that in radium we have a very valuable means of treating malignant growths if we can use it properly, —. Progress in this direction has been very rapid lately, and the fact that in a few cases we can completely and permanently eradicate cancer of the rectum or anus without leaving any damaged tissues, and without the necessity of a colostomy, proves that success is possible. If a cure can be obtained once, it is obvious that it can be obtained many times if we can get the technique of its application right, and this should encourage us to persist with this method of treatment."

In the chapter on precancerous conditions not only is multiple adenomata included,

but also single adenomata,

If a book by so outstanding an author as Mr. Lockhart-Mummery needs a recom-mendation then we do most heartily recommend this work as one of the best on the subject.

CHARLES GOLDMAN

Methods of Treatment. By Logan Clendening, M.D. Fifth edition. Octavo of 879 pages, illustrated. St. Louis, C. V. Mosby Co., 1935. Cloth, \$10.00.

This book, now in its fifth edition, having stood the test of time, has won for itself a

unique position among medical books of its kind. Between its covers one can find practically every form or type of treatment now used in the practice of medicine. Great care has been taken to make it of practical value from the standpoint of technique employed in the administration of drugs. For this reason it should appeal to internes and those who have little experience in modern therapy. Intravenous medication, spinal and cisternal puncture, artificial pneumothorax, duodenal drainage, moidoscopy, therapeutic use of adhesive tape, blood transfusion, and numerous other procedures now fully established as essential to the expert training of the doctor of today, are carefully and thoroughly explained.

The chapters on "The Application of Therapeutics to Particular Diseases" are concise, meaty, and devoid of unessentials. It is not possible for any author, in a volume of this kind, to offer an encyclopedic array of treatments sponsored by various reliable authorities. He has, however, presented a splendid selection from the best

minds in medicine.

It is always the privilege of the reviewer to find some weak point in the subject matter under consideration, and too often the criticisms are trivial and unwarranted. The author of this book has left very little, if anything, that does not meet with the approval of the well trained clinician. There are instances where a certain subject has not been thoroughly considered, such as poisons, where only a few of the toxicological problems have been dealt with. It would be impossible to give them all.

The most valuable and instructive feature of this volume is that it gives the general practitioner, in concise form, treatment, technique, dietetics, glandular therapy, and all other forms of therapy in a way that is readily understood and comprehensible. The method of presentation and the author's style and command of English makes it a

pleasure to read.

F. Schroeder

Dietetics for the Clinician. By Milton Arlanded Bridges, M.D. Second edition, revised. Octavo of 970 pages. Philadelphia. Lea & Febiger, 1935. Cloth, \$10.00.

This! - '-	٠.٠		thousand
pages .			material
from			urces. In
this edition n	nuch of	the subject	matter has

been augmented and rewritten so that the book continues to remain a good reference work. However, very few general practitioners have the time to avail themselves of the extensive bibliography. It contains close to 400 pages of food tables, sample diets and sample menus. In addition the author has included an extensive bibliography pertaining to the subject. These features make the book a ready reference on diet and a guide to further study. In advising on the various diets, the author uses average portions. In our experience with diet prescription writing, the average portion is construed differently by various people. There is no standard for an average portion. It is hoped that in any future revision, the author will describe all diets and portions quantitatively rather than using just the word, average. This book could easily be divided into two books. One would contain the necessary discussion on diseases and their diets. The other would contain general dietetic and nutritional bibliography, tables, charts and sample menus.

Morris Ant

Principles and Practice of Urology. By Frank Hinman, M.D. Octavo of 1111 pages, illustrated. Philadelphia, W. B. Saunders Company, 1935. Cloth, \$10.00.

This book is a major contribution to the literature of urology. The author, in his preface, says, "At the outset, the objective was the presentation of the principles of urology in a form which would be of practical use to the medical student and the man in general practice. The book was not to be written for the urological specialists except for use by them in the medical education of others. In the end, the book covers in detail the principles of foundation and of practice and is neither a primer nor a compendium. It includes everything necessary for the instruction of the medical student, covers the field completely for the general practitioner, and should prove of interest and value as a reference book to the trained urologist." This very modestly describes the book. The chapters on Biology, Embryology, Anatomy and Physiology are superb. It is the opinion of the present reviewer that this part of the book will stand as a classic for many years.

The clinical principles of urology, including symptomatology, types of examination and methods of making a diagnosis are

presented clearly and concisely.

The various diseases of the uro-gential system are taken up and discussed in a logical sequence and from every angle. The discussions of symptomatology are particularly interesting, since not only are the symptoms noted and described but the underlying factors accounting dividual symptoms are carefully discussed. The outlines of treatment are rather briefly but adequately presented.

The book is very well illustrated and the literary style is delightful, which makes

for easy reading.

The urologic surgeon will note with regret that there was not room in a single volume for any detailed description of operative and other technical procedures. However, the book as it stands is a magnificent piece of work and should be in the library of every urologist, general surgeon and general practitioner.

N. P. RATHBUN

Doctors and Juries. By Humphreys Springstum. Duodecimo of 155 pages. Philadelphia, P. Blakiston's Son & Company, 1935. Cloth, \$2.00.

This brief hand-book deals in main with the legal inter-relation of Doctor and Patient, based upon the substantive and adjective principals of Torts. It should be fascinating and enlightening especially to the physician who is as yet unaware of his legal obligations to the community at large.

The author presents a word picture of the medical profession, off and on the witness stand, giving warning of its pitfalls and the avoidance thereof.

The chapter differentiating expert from opinion evidence is most invaluable to the legal as well as medical fraternity.

It is advisable that all medical practitioners not only read but digest its contents.

S. INGRAM HYRKIN

Elementary Human Anatomy Based on Laboratory Studies. By Katharine Sibley. Octavo of 360 pages, illustrated. New York, A. S. Barnes & Co., Inc., 1935. Cloth, \$4.50.

Viewing this work from the standpoint of a physician one feels great admiration for the author and feels a certain sense of scientific fellowship for those who will learn their anatomy from this text. The contents and terminology are taken from authentic The subject is dealt with thoroughly and the book admirably fills the need for which it is intended.

The text deals not only with myology, osteology and syndesmology but includes the digestive system, organs of special sense

and the ductless glands.

With the definite knowledge gained from a book of this type our teachers of health education cannot fail to become more proficient and enthusiastic in the care and development of the children entrusted to their care. SAMUEL ZWERLING

CHARLES B. TOWNS HOSPITAL

FOR THE EXCLUSIVE TREATMENT OF

ALCOHOLISM and DRUG ADDICTION

This hospital has specialized solely in addictions for over thirty years. Our experience has shown us that best results could not be obtained when associated with any other type of case. Its method of treatment has been fully described in the journal of the American Medical Association and other scientific literature. The treatment is a hospital procedure and provides a definite means of eliminating the craving and the toxic products of alcohol and drugs. Emphasizing the after care and with appreciation of the seriousness of the alcoholic problem we devote the convalescent period to minimizing the possibility of relapse. In the classification of the City of New York hospitals this institution has been granted a special license by the Commissioner of Hospitals for the exclusive treatment of alcoholic and drug addiction.

CORNWALL-ON-HUDSON, NEW YORK A SCHOOL OF DISTINCTION

D S M.B A BRIGADIER-GENERAL, SUPERINTENDENT

Students' Activities

Half way between work and play, various activities of the students are purely voluntary, yet are important in training them esthetically or culturally or in preparing them in other important ways for later life. The boy or girl whose soul thrills to music has a source of pleasure that should be cultivated, and many schools have glee clubs, choirs, orchestras, and bands where the student can have no end of good times and yet receive the right training. There is nothing finer than fine music, and there is nothing much worse than bad music, and the parents of a student musically inclined will do well to look into this part of the school

Another student activity is the school paper or magazine. Many a successful writer has made the start on a school publication. For that matter, however, everyone, even in the most every-day business life, has more or less writing to do, and work on the student periodicals, in school and college, gives ease, fluency, and facility in handling our sometimes rather balky language. The pleasure of being able to dash off a rattling good story or a humorous or serious bit of verse is also one of the joys that help make life worth while.

Debating has in it the fun of a good fight, and brings out the splendid qualities of fast, vigorous thinking, quick repartee, ability to capture and hold an audience, and the rare capacity to take defeat with a smile. All these qualities are invaluable in any kind of career, and a school with well-trained debating teams is the place to develop them.

This is a side of school life that parents sometimes fail to consider, but it may turn out to be of prime importance. Don't overlook it.

The School-Child's Breakfast

Many a child is scolded for duliness when he should be treated for undernourishment. In hundreds of homes a 'continental' breakfast of a roll and coffee is the rule If, day after day, a child breaks the night's fast of twelve hours on this scant fare, small wonder that he is listless nervous, or stupid at school A happy solution to the prob lem is Pablum, Mead's Cereal cooked and dried Six times richer than fluid milk in calcium, ten times higher than spinach in iron, and abundant in vitamins B and G, Pablum furnishes protective factors especially needed by the school child The case with which Pablum can be prepared enlists the mother's co-operation in serving a nutritious breakfast This palatable cereal requires no further cooking and can be prepared simply by adding milk or water of any desired temperature. Its nutritional value is attested in studies by Crimm et al who found that tuberculous children receiving supplements of Publim showed greater weightgain, greater increase in hemoglobin, and higher serum-calcium values than a control group fed farma Mead Johnson & Company Lyansville, Indiana, will supply reprints on request of physicians -Adv

Cvanide Antidote

Sources of cyanide poisoning may be classified into four divisions (1) Suicidal (2) Occupational, (3) Accidental and (1) Homicidal

Approximately ninety per cent of the cases are smeidal in nature. While examide is less frequently a factor in poisoning than mercury or stryclinine, the increasing death rate from this substance causes it to assume importance. There were 134 deaths from evanide poisoning in 1930 and an increase each year up to and including 1933, when there were 416 deaths

Hug, of the Argentine Republic, and Chen, Rose, and Clowes, of the Lilly Research Laboratories, working independently, evolved a combination therapy that has produced excellent results new antidote consists of a combination of sodium intrite and sodium throsulphate. Successive injections of the two solutions are made intravenously The recommended dose for sodium intrite is 03 Gm in 10 cc of water and that for sodium thio sulphate, 25 Gm in 50 cc of water. In cases of relapse one-half of the quantity of each should be This combination is reported to be ten times as effective as methylene blue, one of the most commonly used antidotes Rapidity of death from cyanide poisoning has been justly emphysized yet many cases have been known to linger for several hours. As long as the heart beats, the clinician should consider the case hopeful and lose no time in treating it - 1dz

New Series of Winter Cruises

Endeavoring to meet a growing demand for longer voyages aboard its two large "pleasure-planned" liners, the "Queen of Bernuda" and the "Monarch of Bernuda," two special cruises, one of eight and another of nine days, have been scheduled aboard the "Queen," in addition to the regular Triangle Cruise, James N. Findlay, Passenger Manager of the Furness Bernuda Line, amounced. Never before has the Furness Pernuda Line offered such an extensive program of winter cruises.

Frequently, according to Mr. Findlay, returning passengers have complained that the two-and-a-half-day voyage to and from Bermuda does not allow time to fully enjoy the advantages of the two vessels, both of which were constructed primarily for the transportation of passengers and are the only large ocean liners offering a private bath with every room

even at minimum fare.

Sailing January 6 in her eight-day cruise, the "Queen" visits Nassau and Havana. At Nassau, the resort-capital of the Bahamas, a full daylight day is allowed ashore with ample opportunity to visit the resort's famous beaches and show places. Leaving Nassau that evening the "Queen" makes a fast run to Havana, arriving at 2 P. M. the following day. With the steamer as headquarters, two days and a night are spent in the Cuban capital.

January 16 the "Queen" sails on one of her famous seven-day Triangle cruises to Bermuda and Nassau. On this voyage a full daylight day is spent in Bermuda and an afternoon and an evening are allowed in Nassau. The third spectacular trip starting January 23 is a nine-day itinerary that includes Bermuda and Havana, with a day in Bermuda and twenty-seven hours to enjoy Hayana's Casino, cabarets,

night clubs and sightseeing.

Special entertainment programs at sea have been arranged, to make the cruises particularly attractive. Aboard the "Queen" there is every luxury and facility for pleasure and enjoyment, including a \$250,000 dance floor, a tiled swimming pool, gymnasium, several cafes and cockail bars, and an unusually large sports deck running unobstructed the full width of the ship.

A Duplicate of "Warm Springs, Georgia" Pool for Atlantic City

President Roosevelt's approval has just been granted for the building of a duplicate of the famous "Warm Springs, Georgia" pool in Atlantic City. It will be built at a cost of \$35,000, in conjunction with the Betty Bacharach Home for Crippled Children and will have a 150-bed capacity. Infantile paralysis victims treated here will have the benefits of one of the best equipped and most modern pools in the country.

The purified and warmed salt water is changed every three hours while violet ray lamps are trained upon the water at all times. The overhead trolleys will be of untold advantage in aiding the sufferers, by a hanging strap arrangement, to exercise their limbs in an upright position.

Travel Brevities

Among the guests at the Elbow Beach Hotel in Bermuda, recently, were Dr. and Mrs. Herman Schucart, New York City; Dr. and Mrs. Norman D. Samson, Kearny, N. J.; Dr. and Mrs. Alfonso L. Algorer, Brooklyn, N. Y.; Dr. and Mrs. H. Leslie Salov, Newark, N. J.; and Dr. A. M. Wehenkel, Detroit, Mich.

Among the New Yorkers, passengers aboard the "Queen of Bermuda" on a December voyage, were Dr. and Mrs. Warren Hildreth.

Dr. M. F. Steenberg, Dr. Alan Leslie, and Dr. Sidney Silverstone, of the Mount Sinai Hospital, New York City, took a well-carned rest at the Inverurie Hotel in Bermuda during December.

With the recent opening of the ice rink in the Convention Hall at Atlantic City, ice hockey and ice skating have been added to the already diversified list of sports to be enjoyed at that resort. The city's widely known ice hockey team, the Sea Gulls, recognized as one of the greatest non-professional teams in America, meet hard hitting, fast skating opponents every Priday night. The rink is available for public skating every afternoon and evening, while salt water pools, horseback riding, bicycling, wrestling, boxing, and basketball contests, are other diversions available for the mid-winter vacationists at the "World's Playground."

An informative and rather interesting booklet on tropical trips for the season 1935-36, is distributed by the Atlantic Coast Line. Representative Southern resorts are briefly described. Golf courses, hotels, and boarding houses are listed. Fares and other information pertaining to the railroad are included also to make the "guide" as helpful as possible to the prospective traveler and vacationer. In all, it is well illustrated and a very handy directory to keep on file. A copy may be obtained by applying to the General Eastern Passenger Agent's offices in New York City, or through the Travel Department of the New York STATE JOURNAL OF MEDICINE.

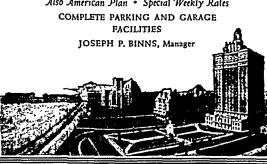

There is no charge for any service rendered by the Travel Department of your JOURNAL. If you have no travel agent, conveniently located, this department can be of assistance.

Castles in Spain...

For all their fame, legendary "Castles in Spain" have their limitations. Where could you find one, for instance, with its own golden beach and a shimmering tropic sea at its very doorstep? With whispering palms touched by magic moonlight? With the Miami area's parade of sunshine pastimes and carefree diversions from which to choose your entertainment? Here, at the Pancoast is a "Castle in Spain" that looks the part . . . light, airy, Spanish architecture,

ARTHUR PANCOAST, President

patios and terraces, decorative tile. Traditions of unexcelled cuisine and friendly service add the final touches of practical well-being to glamorous vacation days. Select clientele assures you of congenial companions for gay days and tropic nights. After all, "Castles in Spain" are only legendary... but the Pancoast is actual... is alive! So much so that it is advisable to write or wire well in advance for reservations.

GENERATIONS

Great Western

MERITS THE CONFIDENCE OF THE PROFESSION

SOME of the reasons for its continued acceptance are:

- Quality and Purity.
 Great Western Champagnes are made by the true French method of slow fermentation in the bottle, taking years of time.
- Only American Champagne to win medals in Paris, Brussels and Vienna.
- Because it is made in America you don't pay for import duty, ocean freight, etc.

Good stores everywhere are ready to serve you. Write for our booklet, "The Art of Serving Wines and Champagnes." Address Dept, NYM-1, Pleasant Valley Wine Co., Rheims, N. Y.

ACID RESISTANCE

WITH

Kalak

Hypertonic - Alkaline - Carbonated - Not Laxative

The years of experience with physicians who have used Kalak show that the use of a formula containing calcium, magnesium, sodium and potassium salts represents a correctly balanced solution. This is Kalak which, as such, aids in maintaining a balanced base reserve.

How Alkaline Is Kalak?

One liter of Kalak requires more than 700 cc. N/10 HCl for neutralization of bases present as bicarbonates. Kalak is capable of neutralizing approximately three-quarters its volume of decinormal hydrochloric acid.

KALAK WATER CO. OF NEW YORK, Inc.
6 CHURCH STREET NEW YORK CITY

IMPORTANT

TO ADVERTISERS IN MEDICAL JOURNALS

and

TO EXHIBITORS AT CONVENTIONS

THE ANNUAL CONVENTION OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK, AT THE WALDORF-ASTORIA, APRIL 27, 28, 29, 1936, will be the largest gathering of physicians in the East this year, by far the greatest convention ever held by the medical profession of this state, and offers advertisers and exhibitors an unusual opportunity in promoting the value and use of their products or service.

EXHIBITORS will have the prospect of reaching in person the greater portion of 13,986 physicians of Greater New York, many of the 8,027 up-state physicians, as well as hundreds from neighboring states. Every exhibit will be described in the program which appears in the April 1st issue of this Journal, and exhibitors will find it an advantageous tie-up to use advertising space in this SPECIAL CONVENTION NUMBER. Three months prior to the convention, 80 per cent of the exhibit space has been assigned—those who have not reserved space will find it advisable to do so at once.

ADVERTISERS should plan immediately for the space and copy they will use in the SPECIAL CONVENTION NUMBER OF THE NEW YORK STATE JOURNAL OF MEDICINE scheduled for APRIL 1, 1936. Regular advertisers will find it profitable to increase their space as the additional number of advertisers using this issue may subordinate their usual advertisement, and the importance of this particular issue to the physicians increases the attention value and the opportunity to impress subscribers as well as the thousands of additional readers receiving the SPECIAL CONVENTION NUMBER.

THEOCALCIN

BILHUBERCORP

In angina pectoris Theocalcin is often employed for a prolonged vasodilator action on the coronary vessels, or to guard against constriction and reduce the frequency and severity of painful attacks. Treatment is best begun with 2 or 3 tablets several times a day; then the improvement may be continued with smaller doses

THEOCALCIN (theobromine-calcium salicylate) Council Accepted

Available in 7½ grain tablets and as a Powder

BILHUBER-KNOLL CORP. 154 OGDEN AVE., JERSEY CITY, N.J.

Why Advertisers Use Your Journal

If an advertiser sent a salesman to make a personal call on each of the 16,770 renders of the New York State Journal of Medicine—and he averaged ten physicians a day—it would take him over five years to contact the entire circulation. The expense would run into an enormous figure for the one call on each doctor—soon forgotten.

At a cost of only $8\frac{1}{2}$ cents per physician, maximum, an advertiser is in touch with every one of the 16,770 prospective buyers TWENTY-FOUR TIMES A YEAR!

The JOURNAL is the advertiser's most economical means of introducing and maintaining a product or service before the profession. It provides the way of giving equal opportunity and privilege to every doctor, and helps demonstrate the advertiser's belief in the service, product, or equipment offered. . . .

... reasons why more than 300 advertisers used the JOURNAL last year.

Solutions of Knox Gelatine are filtered and concentrated in vacuo. Even the air used for drying is filtered.

Analysis Knox Gelatine

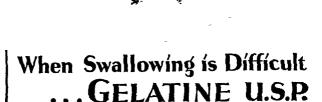

Protein (14 amino acidi) 85 0-86 0% Calcium Phosphare 1.0-1.25% Fat (Less than)

Moisture 13.0-140% Carbohydrates Nil

Bacteriologically safe...pH of about 6.0... odorless...no carbohydrates ... made as carefully as an ampule solution.

Of interest in the treatment of muscular dystrophy is the 25% glycine (amino-acetic acid) in Knox Gelatine

A Soft, Non-Irritant Food

IN post-tonsillectomies, adenoidectomies; after tooth extraction; in pharyngitis and other instances where swallowing is difficult, gelatine can be used as a vehicle for many soft, non-irritant dishes. These may be swallowed with a minimum of effort, giving the inflamed areas an opportunity to heal. The soft smoothness of pure gelatine is also valuable in acute or chronic stomatitis.

Knox Sparkling Gelatine surpasses in all respects the minimum U.S.P. standards of purity. It contains 85% of protein which is readily digested and assimilated.

Quite a remarkable product—Knox Gelatine. Made as carefully as an ampule solution. Valuable where additional protein is required in the diet of the convalescent, the tubercular, diabetic or post-operative patient.

Pneumonia Typing is Simple!

IAGNOSIS-pneumonial Pneumococcus pneumonia? Is serum therapy indicated? That depends on the type of the causative pneumococcus.

The physician calls for Rapid Typing sera Lederle, Types I and II, the types for which" Council-Accepted" therapeutic sera are available. Microscopic examination of a fleck of the patient's sputum mixed with the required amount of specific typing sera, reyeals typical changes in the capsule-Neufeld reaction -in the mixture that identifies the type. These changes consist of a swelling of the capsule with a sharp definition of outline.

All in a few minutes! And therapeutic serum administration may be begun at once. Pictures of the significant capsular swelling are in the direction sheets in the Lederle packages. (If no such capsules are found, the efforts to identify the type can be carried further. Lederle has Typing sera for 29 types of pneumonia but full use of the series is usually regarded as requiring special technical training.)

Early administration is essential to secure the radical reductions of average mortality obtainable

with serum therapy.

PREVENT KETOSIS OF PREGNANCY WITH KARO IN THE PRENATAL DIET

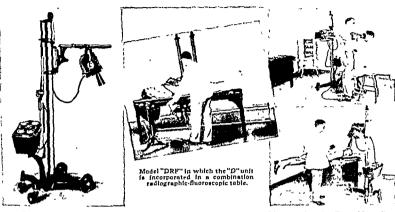

ee Enlarging of the uterus often causes reflex vomiting. Unless carbohydrate is taken throughout the day to maintain the blood sugar at high levels, Ketosis results. This disturbance aggravates the vomiting, frequently beyond control because of the inability of the damaged liver in pregnancy to resist Ketosis. **

-Kugelmass, Clinical Nutrition in Infancy and Childhood (p. 53)

KARO is an ideal carbohydrate to combat Ketosis. Karo consists of palatable maltose and dextrose (with a small percentage of sucrose added for flavor) quickly absorbed and the non-fermentable dextrins that are gradually transformed into simple monosaccharides. Karo can, therefore, be fed in larger amounts than simple sugars without danger of digestive disorders—fermentation, distention, diarrhea...Karo may be added as Syrup or Powder to milk, cereals, gruels, fruits, vegetables, desserts and refreshments. Whatever the prenatal dietary indicated, Karo will furnish the mixed sugars necessary to combat Ketosis. And the earlier in pregnancy the addition is made the less the danger of Ketosis.

WHAT OIL-IMMERSED X-RAY APPARATUS HAS CONTRIBUTED TO OFFICE PRACTICE

Model "D" Mobile—compact, conserves floor space, and can be operated in any part of the building by plugging in to the nearest electric service outlet.

Fluorescopic and radiographic applications of the Mobile D', showing how the office examination couch can be utilized to advantage.

• The principle of G-E shock proof x-ray apparatus differs radically from all other principles ever applied to x-ray design, in that the entire high voltage system, including the x-ray tube itself, is immersed in oil.

So successful has this type of apparatus proved itself over a period of twelve years, that today finds the same principle applied to G.E. x-ray apparatus of capacities as high as 300,000 volts. It has made operation of diagnostic x-ray equipment 100% electrically safe, unaffected by atmospheric conditions, comparatively simple to operate, and convenient to apply. Thus a physician may consider the use of such a diagnostic x-ray unit in his office as thoroughly practicable.

The "D" Series of G-E shock proof

The "D" Series of G-E shock proof x-ray units is popular not only among general practitioners but also in some of the specialty practices, where the range of diagnostic service here provided finds wide adaptability. For example, a radiograph of the average size pelvis is obtained with a one-second exposure, using the Potter-Bucky diaphragm at 30-inch distance; exposure values of other parts

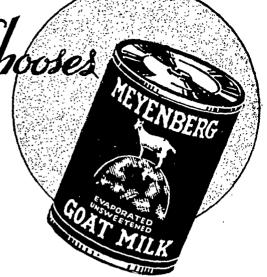

of the body as short as % second. The quality of the resulting radiographs leaves nothing to be desired.

If you have been foregoing the advantages of x-ray diagnosis in your practice in the belief that it involves electrical hazards and other complications in application, the possibilities offered you in the G-E Model "D" series will prove a revelation. We'll be glad to send you descriptive literature without obligation—on receipt of the coupon below:

The Doctor Chooses

And every month more and more physicians are choosing Meyenberg Evaporated Goat Milk for their Food Allergy, Tuberculosis and difficult pediatric cases.

BECAUSE

Goat milk protein is non-allergic and forms a fine, easily digested curd, and

BECAUSE

The fat in goat milk is in fine globules of easily saponified oleates, and

BECAUSE

The minerals of goat milk are in splendid proportion and quantitatively high, and

BECAUSE

Meyenberg Evaporated Goat Milk is easily available, economical and bacteria-free.

If, so far, you have not chosen Meyenberg Evaporated Goat Milk, Doctor, send for the generous clinical size and descriptive literature.

INDIANAPOLIS, INDIANA, U.S.A.

THERE ARE MANY PATIENTS who, because of the strain of high-pressure living, are troubled with problems that rob them of sleep Failure to sleep increases their anxiety until it seems that life itself is threatened. For these patients, regularity in retiring and the use of a safe, effective hypnotic and sedative for a few nights will restore them to a condition where normal sleep is possible.

The induction of calm, restful sleep is accomplished safely and effectively by the use of Ipral Sodium. The action of Ipral Sodium (sodium ethylisopropylbarbiturate) is fairly prompt and free from cumulative effect, for it is readily absorbed and rapidly eliminated. When administered in therapeutic dosage, it is non-toxic and produces no digestive disturbance or other untoward organic effects

IPRAL SODIUM is supplied in 4-gr. tablets as a sedative, 2-gr. tablets for use as a sedative and hypnotic and in 4 gr. tablets for pre-anesthetic

medication When there is pain involved TABLETS IPRAL AMIDOPYRINE (2 gr. Ipral, 2.33 gr. Amidopyrine) provide both a sedative and an analgesic effect.

Both of these Squibb Ipral Products may be obtained in vials of 10 and bottles of 100 and 1000 tablets For literature address Professional Service Department, 745 Fifth Avenue, New York.

CONSIDER THIS MATTER OF SUPPORT

ANY physicians agree that there are certain situations in which the muscles and con nective tissues are unable to do their work, as for instance-in some cases of pregnancy, visceroptosis, hernia, sacro-iliac disturbances, postoperative con ditions and the like When either abdominal or back support is deemed by the physician requisite to a return to physiologic balance.. and a fabric garment is prescribed for this purpose.. the great difficulty-it will be admitted-is to secure supports that are scientifically constructed, reasonably priced and properly fitted to the individual It has been the definite objective of S H Camp and Company for over a quarter of a century to manufacture supports with these qualifications

The attainment of these three desiderata has involved many busy years of research and collabora tion with leading surgeons, gynecologists, obstetri-cians, internists and orthopedists. To heed the stern dictates of eminent physicians for trial and retrial, to adhere to Camp standards of quality of merchan dise and workmanship, and at the same time to keep manufacturing costs-and therefore retail pricewithin reasonable bounds has represented an achieve

ment of no mean proportions

To insure the proper fitting of supports, to acquaint the profession with Camp models and to keep both physicians and fitters apprised of new garments, it has been necessary to establish the Camp Professional Support Service With the development of this Service and the excellence of Camp Supports has been won the approval of such organizations as the American Medical Association and the American College of Surgeons

In the announcements which are to be featured this year, we propose to explain in detail the various phases of the Camp Professional Support Service

and how each factor in the Service helps to solve this matter of supports and to provide garments which are scientically constructed reasonably priced and properly fitted to the individual

Symposium on Sympathetic Ophthalmia

INSTRUCTIONAL HOUR Notes on Pathology and Surgical Treatment

BERNARD SAMUELS, M.D., New York City

The subject of this paper is one of great practical importance because on the correct judgment of the surgeon, in cases of injury, the future vision of the patient may depend. It has been known for a long time that if one eye has received a perforating wound occasionally the other eye, which was hitherto sound, may be affected by an inflammation of a malignant nature, leading to atrophy and blindness. Since no other cause for the involvement of the second eye than the injury of the first is found, the disease has come to be called sympathetic ophthalmia. This disease does not occur when the wound in the injured eye heals correctly and when the function of the eye is not interfered with. The disease supervenes in the uninjured eye only when the first eye shows signs of iridocyclitis as a result of traumatism. From clinical observation it is known that not all eyes that suffer from traumatic iridocyclitis excite sympathetic ophthalmia. However, it is realized that the enucleation of the injured eye is the one certain means of insuring the safety of the other. If we observe, after a perforating wound, that the eye becomes soft and atrophic, that the cicatrix on the surface is retracted, that the eye is painful or sensitive to touch, and that the vision is failing, we find in these symptoms an indication for enucleation, because such an eye has the potentiality of producing sympathetic

ophthalmia. One cannot predict positively that it will do so but it may.

In those eyes that have excited inflammation in the fellow eye there is found a peculiar and specific lesion that distinctly differs from that of the familiar traumatic endophthalmitis anatomically and in its consequences. If we place in one group globes that have been removed for fear of producing sympathetic ophthalmia and if in another group we place globes that. have really excited sympathetic ophthalmia and that have been excised in the hope of shortening or curing the disease, we find in the latter group, in addition to the features of common iridocyclitis, a peculiar infiltration in the choroid. In endophthalmitis we are not accustomed to see evidences of irritation in the choroid because this layer is protected by the retina from toxins originating in other structures. Sympathetic ophthalmia is pre-eminently an infiltration in the uveal tract, showing in a singular way no tendency to form exudates on its surface. We must never forget that the infiltration in the ciliary body and iris is always combined with another disease, iridocyclitis due directly to the injury in this region. As a result of the endophthalmitis, which precedes the infiltration, cyclitic membranes on the surfaces of the ciliary body and iris are formed. One looks to the choroid to find the characteristic infiltration developed in its purest form because

From the Department of Surgery, New York Hospital, and the Eno Laboratory, New York Eye and Ear Infirmary, New York. This paper is a summary of remarks made in a demonstration of anatomic preparations before the Section on Ophthalmology and Oto-Laryngology at the Annual Meeting of the Medical Society of the State of New York, Albany, May 14, 1935

the posterior segment of the eye is seldom damaged by the injury so that the infiltration here is not complicated by the

presence of a separate disease.

The infiltration is composed chiefly of lymphocytes, which first appear in and around large veins, destroying their walls and invading and occluding their lumina. The focal accumulation of lymphocytes in the adventitia of the veins is a distinguishing point in sympathetic ophthalmia, even when epithelioid and giant cells are absent. Epithelioid cells, which are larger than lymphocytes, have an oval vesicular nucleus and a protoplasm staining with eosin. They are so-called because they correspond exactly to the elements bearing the same name in tuberculosis. Where epithelioid cells appear in numbers they show a tendency to coalesce, the outlines disappearing so that the protoplasm becomes confluent and the whole is transformed into a giant cell. Epithelioid cells are present in small groups in the midst of broad fields of lymphocytes. In some places the nests are round and in others elongated. In reality it appears that these groups are strands and that it depends on the direction of the section whether they manifest themselves in round or drawn out islands. Epithelioid cells are thought to be derived from a proliferation of the cells in the walls of blood vessels. The entire infiltration takes place in the layer of large blood vessels of the choroid and in the suprachoroidal lamellae. In the latter, in the early stages, solely lymphocytes are found because there are no blood vessels to degenerate. The infiltration develops in the following stages:

1. Stage of lymphocytic infiltration in the walls of the large veins of the uveal tract. The infiltration in the vortex veins often presents a broad, dense lumen of perivasculitis.

2. Stage of the formation of typical nodules with giant cells in the center surrounded by epithelioid cells and lympho-

cytes.

3. Stage of the formation of tumorshaped masses of granulation tissue in the uvea, composed of the above mentioned cells. Tumor-like formations are more apt to be found in the iris than elsewhere, whereas the charoid undergoes a uniform thickening, which may be three or four times as great as the original layer. In excessively developed cases the infiltration of the entire uveal tract may reach such proportions as to occupy almost the entire cavity of the globe, and all of this may take place in the short space of a few weeks.

Singularly the choriocapillaris is free of infiltration. One will always notice a compressed pinkish streak on the internal surface of the choroid, under the pigment epithelium, which contains none of the intensely stained lymphocytes seen in the deeper layers. The pigment epithelium itself may present small moundlike projections on its surface—the so-called foci of Dalen—composed of cellular elements that have wandered through the lamina vitrea and of cells from the pigment epithelium.

Having regard to the other divisions of the uveal tract, in the ciliary body the infiltration is confined to the vascular layer, a nodule in the muscle being a rare exception. No matter how thick and dense the infiltration in the vascular layer may be the unpigmented ciliary epithelium goes uninterruptedly over it, so that the infiltration may be said to be still confined to the uvea. When a search for giant cells is made they are more likely to be seen in the ciliary body than elsewhere. Here and there throughout the uveal tract giant cells containing stroma pigment are sometimes encountered; such cells are believed to have their origin in chromatophores.

In the iris the infiltration, no matter how exuberant, is invariably covered on the corneal side by the intact anterior limiting layer. On the other hand, posteriorly typical nodules break through the disintegrated pigment epithelium and expand on the lens capsule, causing the posterior synechia associated with sympathetic ophthalmia. The sphincter muscle, as in the case of the ciliary muscle, is often identifiable even when all else of the stroma is replaced by the infiltration. The presence of plasma cells and eosinophiles in connection with the characteristic elements of the infiltration in the iris and ciliary body is sometimes mentioned in descriptions, but these cells are in no way essential to the picture of sympathetic ophthalmia; rather they are an expression of an accompanying chronic iritis or cyclitis as a result of the injury.

Prolapsed portions of the uveal tract may reveal the most exuberant type of infiltration. Covered by the conjunctiva and having a grayish blue color such masses simulate staphylomatous areas at the seat of the wound. No detached tag of uveal tissue, wherever it may be, as for instance strands of the perichoroidal lamellae clinging to the sclera when the choroid is separated, or ragged particles of uvea isolated on the surface of the globe near the wound, ever escape the infiltration.

Bearing in mind that the uvea is the primary seat of sympathetic opthalmia, it is interesting to consider its manifestations in other structures of the globe. The sclera, having everywhere uveal tissue as the lining of its internal surface, is many times inflamed to a surprising extent, so much so that in severe cases one is justified in thinking of sympathetic ophthalmia as a chorioscleritis. Long stretches of the lamina fusca may be involved in an internal scleritis, files of lymphocytes separating the bundles. The infiltration appears along the extensions of the uveal tissue that line emissaria, within the lumen of which there may be giant cells and often epithelioid cells are present ensheathing the vessels. Spreading on all sides from the walls of the emissaria files of lymphocytes not infrequently appear in the middle layers of the sclera. Around the external openings of emissaria, sympathetic nodules may develop, in connection with which the outer layers of the sclera may show a lymphocytic infiltration-external scleritis. Typical nodules in the tissues of the intervaginal space and even in the substance of the nerve have been reported by A. Fuchs. Nodules have been identified between the fibers of the inferior oblique, not only at its insertion in the sclera but also at a considerable distance away. It is not possible to say to what extent the orbital tissues may be affected because evisceration is not performed in this disease, but from the frequent involvement of tags of tissue adhering to the globe one gleans that the specific infiltration may be more far reaching than hitherto suspected. The narrow zone of the fibrous tissue just external to the limbus, where the tissue is relatively thin to accommodate the external and internal

sulcus, merits special description on account of its proximity to the root of the iris which is a favorite spot for excessive development of the infiltration. ularly when the angle of the chamber is filled with infiltration this narrow vascular zone of the sclera attracts attention in the sections because of its intensely blue stain. brought about by row after row of lymphocytes packed between the layers of connective tissue, splitting them and even destroying them, and producing a regular dehiscence. One remarks on this evidence of histolysis, and this is the only place that ever shows it in such definite relation to the specific infiltration.

In sympathetic ophthalmia the retina constantly presents a dense and heavy infiltration in the walls of the blood vessels (called sympathetic perivasculitis by I. Meller). A nodule in the retina is one

of the rarest findings.

The structure of the globe that is least affected is the cornea which, in contradistinction to the sclera, is not in contact with uveal tissue but is far removed from it. The aqueous and Descemet's membrane would seem to protect the stroma to a certain extent from whatever viritant substances may go with sympathetic inflammation, or it may be that the corneal lamellae have a natural resistance.

In the sympathizing eye the infiltration is of exactly the same character as that in the exciting eye. One would not anticipate seeing membranes on the surface of the uveal tract in the sympathizing eye because there has been no traumatic iridocyclitis to produce them. The sympa-thizing eye is rarely examined because there is no reason for removing it unless the patient dies from another malady or the eye causes so much pain that he prefers to have it excised. It is seldom that the injured eye preserves any vision, in which case it is not enucleated because the sympathizing eye may become blind and we would be sacrificing the last remnants of vision to the patient,

Clinically the diagnosis of sympathetic ophthalmia is made from the symptoms in the uninjured eye. In the injured eye, symptoms of the traumatic iridocyclitis mask the picture and are sufficient to

account for all that we see.

As a rule sympathetic inflammation supervenes within a few weeks after in-

About two weeks is given as a minimum time. Notwithstanding that the disease may break out many years after an injury the infiltration itself always gives the impression of being a recent The examination of many globes leaves the impression that the infiltration flares up almost simultaneously in all parts of the uvea, and yet the anterior infiltration is usually a little older than the posterior. Thus the anterior segment may be in the third stage and the posterior in the second stage. It is certain that the infiltration starts first in the exciting eye and that in a very short time, shorter than the clinical history would lead one to believe, it begins in the fellow eye. As a proof of this brief interval, many eyes that have excited the disease reveal the specific infiltration in the choroid no further advanced than the first stage when there are only scattered foci of lymphocytes in and about large veins. If the interval were a long one we would conclude that the removal of an injured eye at such an early stage in the development of the infiltration in its choroid would prevent the incidence of the disease in the other eye. Very exceptionally the sound eye becomes inflamed several days after the removal of its fellow. From pathologic experience, now and then an eve shows the charactertistic signs in the choroid in the earliest state and yet the other eye never becomes inflamed. Such a condition is termed "pathologic sympathetic ophthalmia"-it being supposed that by chance the eye was removed before there was time for the disease to spread.

Sympathetic ophthalmia is a pathologic process entirely different from septic endophthalmitis—different both clinically and anatomically. Septic endophthalmitis remains localized in the injured eye, the vision of which it destroys but it produces no complications in the fellow eye. Anatomically the distinction lies in the character of the inflammation. The reaction of the tissues in septic endophthalmitis is an exudative one. The cells migrate from the blood vessels and have a high degree of mobility. They can move quickly and get into the cavities of the eye where they form pus. The granulation tissue which forms in the organization of the exudate is situated on the external

surface of the uvea and not in its stroma. On the other hand the cells of sympathetic inflammation show no disposition to leave the stroma. In septic endophthalmitis the ciliary body and iris are inflamed but not the choroid. In sympathetic ophthalmia, in addition to the inflammation in the ciliary body and iris, we find the choroid infiltrated, without any apparent reason.

Many of the anatomic characteristics of sympathetic ophthalmia are closely related to that group of inflammations called granulation tumors. Such a tumor is a new growth that consists of granulation tissue that has an aggressive power. Granulation tumors have no tendency to transform themselves into cicatricial tissue but rather a pronounced tendency to degeneration. There are principally three diseases that belong to this group—tu-

berculosis, syphilis, and leprosy.

From a purely histologic standpoint the similarity between tuberculous and sympathetic ophthalmia is very strong. The same types of cells compose the infiltration in each disease, although there is a difference in the manner of arrangement and distribution. In sympathetic ophthalmia the infiltration is more uniform in the choroid than in tuberculosis where it is more nodular. In sympathetic ophthalmia the emissaria almost invariably even in the mildest cases show an infiltration; but in tuberculosis this is seen only in very severe cases. The distinguishing feature in the iris is the preference of for the anterior tuberculous nodules layers, leaving the posterior surface free, so that the movements of the iris are but little interfered with. Early and complete posterior synechia characterize sympathetic inflammation. The outstanding difference between the two diseases is the manner in which the infiltration in each behaves toward the other tissues of the Tuberculous infiltration possesses a histolytic action by which it destroys the densest structures. If it starts in the iris it will gradually fill the anterior chamber and on coming in contact with the cornea and sclera it will melt them, so to speak, producing an excavation in them of the same size and shape as the tumor itself. This destructive malignancy is not noticed in sympathetic infiltration which only extends beyond the uvea along preformed channels, as the emissaria, lined by uveal

tissue. Cascation typifies all tuberculous infiltrations, and while it is not often seen in sympathetic infiltration, it is well to remember that focal necrosis does occur, There is no doubt that the infiltration in tuberculosis is an expression of reaction on the part of the uvea to acid fast bacilli but no micro-organisms are demonstrable in sympathetic infiltration. It is true that J. Meller and his school believe that the disease is caused by the tubercle bacillus. They report success in isolating the bacillus in the exciting eye and in the blood of patients afflicted with sympathetic ophthalmia. The question is open to controversy.

The pathologic anatomy explains the intractability of sympathetic ophthalmia and its utter hopelessness when the infiltration is fully developed. As a rule it is useless to attempt treatment of the exciting eye because of its soft and atrophic condition. The infiltration in the sympathizing eye may cause an increase in tension, especially in the sympathizing eye, because of the enormously thickened root of the iris and the complete posterior synechia. Great difficulties arise in any endeavor to reduce the tension. Atropine, if it could act in the presence of so much infiltration, would increase the tension by bringing more tissue into the angle, and pilocarpine would make the synechia more complete at the pupil. Surgically an iridectomy is out of the question; neither may a cyclodialysis be made because the ciliary body is often highly infiltrated and hemorrhages would take place from the rupture of engorged vessels. No form of sclerotomy is permissible since scleritis is

a common complication of sympathetic ophthalmia. From the surgical standpoint the cornea is the only field of the globe that is available for operation because of its freedom from inflammation, Repeated paracenteses are of great value in the relief of the secondary glaucoma in the sympathizing eye. They should be made well away from the inflamed and dehiscent zone at the limbus.

Sympathetic inflammation is remarkable above all else for its chronicity. It is only after years that the infiltrated areas in the uvea are converted into membranes. No attempt should ever be made at cataract extraction or at making openings in the iris unless there is a definite reason and only then provided that the eye has been quiescent for a very long period. The reaction does not set in at once after an operation but gradually a plastic exudate is poured out that bridges over any artificial opening that has been made for optical purposes.

Finally, in the matter of preventive measures, an evisceration may be ineffectual because it is not possible to remove the uveal extensions in the emissaria. It is the practice in the Vienna school to excise all phthisical globes after panophthalmitis because pathologic experience teaches that even in these some uveal tissue escapes destruction. In enucleation care should be taken to excise a long strip of the nerve and with it tissues adjoining the posterior segment of the globe. One can never tell how far away from the sclera the specific infiltration may be found.

57 West 57th Street.

SYMPATHETIC OPHTHALMIA AND ITS COMPLICATIONS Surgical Treatment

JOHN F. GIPNER, M.D., F.A.C.S., Rochester

Prophylactic Surgery

The prophylactic removal of severely wounded, hopelessly blinded eyes is the only surgical procedure which can be considered under the above title that gives uniformly happy results, All operations on eyes with sympathetic disease may yield discouraging results because organized exudate tends to obstruct and undo the efforts of the surgeon directed towards restoration of vision.

Every eye which has been severely lacerated or otherwise wounded through the ciliary body should be removed, especially if the patient is a child. If, after consultation with a fellow ophthalmic surgeon, removal of the eye is not deemed necessary, the surgeon caring for the patient becomes responsible for a prolonged series of difficult slit-lamp observations of both eyes of the patient, until the danger of sympathetic disease has passed.

In eyes where the cornea is so damaged that there is no hope for useful vision, even though the ciliary body has escaped injury, it is usually prudent to remove the eye and save the patient a prolonged convalescence and the inevitable phthisis bulbi which demands subsequent enuclea-

If the prophylactic surgery is performed immediately, before infection has developed, evisceration may be performed in lieu of enucleation. I prefer evisceration with an elliptical sclerocorneal excision. The whole cornea and small lateral triangles of sclera are excised. After thoroughly removing the ocular contents, carefully curetting out all pigment around the emissary vessels, the scleral margins of the wound are brought together by three or four plain catgut sutures. Tenon's capsule and the conjunctiva are united by interrupted, horizontally placed silk sutures. Dr. Sandford Gifford recommends evisceration without resection of cornea according to the technic developed by his father. I have had no experience with this method.

When enucleation is preferred for the prophylactic operation, simple enucleation is always the safest procedure. If the operation is performed immediately after the injury and the danger of infection is very slight, enucleation with implantation of fat, bone pith, cartilege, glass or gold ball into Tenon's space may be done. In this operation, after simple enucleation, the implant is inserted into Tenon's space, the recti muscles are sutured over the implant and Tenon's capsule and the conjunctiva are united. Silk or ten-day triple A chromic catgut may be used for the buried sutures. Mules' operation, or opticociliary neurectomy with glass or gold ball implantation into the scleral envelop is not recommended as it is not without danger of sympathetic disease even in uninfected eyes.

Removal of the Exciting Eye

Having elected to wait and watch the progress of the case, one should be prepared to enucleate the exciting eye at the first signs of sympathetic inflammation in the sympathizing eye as determined biomicroscopically. If one does not have access to a slit lamp, the patient should be referred to someone who can and will

make frequent conscientious slit lamp examinations. In this way some eyes may be saved which otherwise might better be enucleated.

When the first early positive biomicroscopic signs of sympathetic disease are seen, immediate enucleation of the exciting eye is imperative. Evisceration must not be performed now because the disease in the exciting eye is not only in the uvea, but also involves the sclera by way of the emissary vessels and nerves. Simple enucleation is again the safest procedure, although one may implant into Tenon's space in selected cases, where, in the surgeon's judgment, only slight or no extension of the disease into the sclera has occurred.

Should the patient present himself in the stage of fully developed sympathetic disease, it may be advisable not to enucleate the exciting eye if useful vision is present. Once sympathetic disease is established, sacrifice of the exciting eye has little or no effect on the course of the disease in the sympathizing eye.

All of these operations may be performed under either local or general anesthesia. Two per cent novocaine combined with preoperative sedation with sodium pento-barbital, gas ether, rectal or intravenous avertin, or intravenous Evipal may be employed. Evipal gives immediate complete anesthesia for fifteen to twenty minutes, which is long enough for any of the procedures mentioned.

Surgical Relief of Secondary Glaucoma

Sympathetic uveitis runs the same course in both the exciting and the sympathizing eye. Glaucoma may result from extensive posterior synechiae which develop even with the pupil widely dilated. If the intraocular pressure rises acutely, or if it rises and stays persistently above twenty-eight millimeters (Schiotz) for a week or more without signs of regression, a broad base iridectomy should be made. This may be difficult if the iris is necrotic and friable. Several attempts may be necessary to pull out and resect a sufficient quantity of iris base to open up the drainage angle of the anterior chamber. If seclusion of the pupil with iris bombe is present, transfixation of the iris may be preferred to iridectomy, as a temporary

measure at least when the slightest surgical trauma is desired.

To transfix the iris, a Graefe knife is pushed into the anterior chamber one millimeter to the inner side of the temporal border of the cornea, passing through and through the iris, over the pupil and through and through the iris and out through the cornea at a corresponding point on the other side. When the knife is withdrawn, four openings are made in the iris which may remain open and lower the intraocular pressure, or they may become closed over by organizing exudate. Iridectomy should then be done as there is less likelihood for this larger opening at the base of the iris to become sealed over with exudate. Because of the rich production of organizing exudate in sympathetic ophthalmia, filtration operations are not useful in combating this disease. However, a La Grange sclerectomy may occasionally be combined with the iridectomy to produce a more effective control of the glaucoma.

Cyclodialysis may also give temporary relief in certain cases where iridectomy has failed, but it is of little value for the production of permanent reduction of intraocular pressure in these cases.

Extraction of Cataracta Complicata

The cataract which develops in sympathetic disease should not be removed until all signs of active inflammation have subsided. This will be many months or more than a year after the onset of the disease.

If the iris adhesions are minimal, they are broken down by passing a narrow, thin, flat spatula between the iris and lens through the iridectomy openings, and sweeping the spatula completely around under the iris. In doing this the line of cleavage may occur below the anterior lens capsule rather than above it. If this happens, the thickened anterior capsule can be excised by two converging cuts with straight scissors or pince-ciseaux inserted into the anterior chamber. After having made sure that the capsule opening is adequate with a cystotome, the lens is removed by expressing it as in the regular capsulotomy cataract operation.

If the iris can be separated from the lens capsule, capsulotomy with capsule forceps or cystotome is performed and the lens is extracted as in an uncomplicated case.

When the organized exudate uniting the iris and anterior capsule is very thick, the Wenzel-Wecker operation may be performed. The incision is made with a Graefe knife, but on entering the anterior chamber, the iris is pierced with the point of the blade. The knife is passed behind the iris through the lens capsule to the opposite side and the counter-puncture through the iris and cornea is made. The incision is completed with sawing movements, making a flap in the adherent iris and capsule as well as in the cornea, If the opening in the capsule is large enough, the lens is expressed with a lens hook or Daviel spoon. The flap of iris is then excised by two converging incisions with scissors or pince-ciseaux.

The intracapsular extraction operations can not be performed in late sympathetic disease because the organized exudate thickens, reinforces and strengthens the fibres of the zonular ligament so that they can not be ruptured without excessive trauma.

Procedures to Reopen Pupil

If the injury to the exciting eye has damaged the lens, partial or complete absorption of the lens results, depending upon the amount of physiological sclerosis present. There then remains a thin membraneous cataract adherent to the iris in young patients, or a dense membranous cataract in older patients. Membranous after-cataract also remains after a cataract has been extracted surgically in these cases.

The Ziegler discission is ideal for most thin membranous cataracts with adherent iris. The Ziegler knife-needle is entered at the limbus above with the cutting edge parallel to the margin of the cornea. It is pushed downward to a point three millimeters from the limbus, and three millimeters laterally from the vertical meridian where it is rotated so that the cutting edge is toward the iris. The point is quickly thrust through the iris and an incision is made with sawing movements obliquely upward to a point near the entrance of the knife-needle, avoiding a loss of aqueous. The knife is raised above the level of the iris, rotated on the flat and swung across the anterior chamber to a

point which lies three millimeters from the limbus and four millimeters laterally from the vertical meridian of the cornea. The point of the knife is now quickly thrust through the iris and with sawing movements the incision is carried upward to meet the upper end of the first incision; a V-shaped iridocapsulotomy results, with apex upward. The Ziegler discission knife will not cut thick membranes, and in such cases should be replaced by Wheeler's discission knife, which, because of its weight and length of blade, can be made to cut thicker membranes.

Although I prefer the Ziegler operation because of the slight trauma to the eye and the smallness of the corneal wound which retains fluid vitreous, the De Wecker pince-ciseaux entered through a keratome incision may be used to make a simple iridocapsulotomy, iridotomy or capsulotomy depending on the conditions which are present. A V-shaped incision can also be made with pince-ciseaux through the corneal keratome incision. Care must be taken by the assistant to raise the speculum off the eyeball and so avoid excessive loss of fluid vitreous.

In cases where the incised membrane and iris operated by the above methods fails to gape, an operation to remove a portion of the membrane must be tried. Through a keratome corneal incision a Schnaudigel keratome-punch is thrust through the membrane and a portion is punched out and removed.

De Wecker devised iritoectomy and iritodialysis for these cases. Iritoectomy with the keratome is performed in the upper corneal limbus. The corneal incision should be six to eight millimeters in length. After the aqueous has flowed off, the keratome is pushed through the membrane making an incision equal in length to that in the cornea. With the pince-ciseaux, two converging cuts are made in the iris and membrane so that a triangular piece is excised, and removed with iris forceps. The apex of the triangle should lie somewhat below the center of the cornea.

When iritoectomy is performed with the Graefe knife, an incision is made with cutting edge downward in the lower third of the cornea. The point of the knife is pushed through the cornea and the iris

membrane, is carried over behind the iris, and the counter puncture is made through the iris and cornea. When the section is completed there is a large flap in the cornea and in the membrane. A triangular flap of the membrane is now excised and removed as in the preceeding operation.

Iritodialysis is indicated in cases where the pupil is obstructed while the iris is pushed forward and is partly adherent to the posterior surface of the cornea. An incision, five or six millimeters in length is made with a keratome through the cornea where some anterior chamber remains. The aqueous is allowed to escape and then the keratome is plunged through the iris membrane making a similar cut. Two incisions are now made with pinceciseaux from the two ends of the incision in the membrane diverging downward to the iris base. This square flap of iris is grasped by iris forceps and is torn from its base at the sclera and removed.

All of these pupil restoring operations are accompanied by bleeding from the iris and consequent reaction. Even though the opening in the membrane stays open, the sight in these eyes is practically always impaired because of the degeneration of the vitreous, retina, and optic nerve secondary to the severe uveitis.

Conclusion

In conclusion, I repeat that the most gratifying results in the surgery of sympathetic ophthalmia are not obtained from eyes with sympathetic disease, but in eyes removed as prophylaxis against the disease. The exciting eye must be removed at the first biomicroscopic signs of sympathetic disease in the sympathizing eye. If the disease is well advanced when first seen, it may be prudent not to remove the exciting eye.

The key note of successful surgery for the complications of sympathetic ophthalmia lies in gentle manipulation and in cutting the iris and the adherent membrane with sharp instruments, without dragging on the ciliary processes.

The drainage angle should be kept open by surgical procedures if secondary glaucoma develops which cannot be con-

trolled medically.

Cataracta complicata from sympathetic ophthalmia should not be removed until all signs of inflammation have subsided.

To reopen a pupil after cataract extraction or traumatic absorption of the lens, the Ziegler discission is best if the membrane is thin. If the membrane is thick, the various operations of De Wecker may be tried or the punch operation may be used to advantage.

SYMPATHETIC UVEITIS

Results of Treatment with Diphtheria Antitoxin in 35 Consecutive Cases

F. H. VERHOEFF, M.D., AND S. R. IRVINE, M.D., Boston, Mass.

From the Howe Laboratory of Ophthalmology, Harvard University and the Massachusetts Eye and Ear Infirmary

Eight years ago the senior writer brought forward as effective treatment for sympathetic uveitis the use of frequent subcutaneous or intramuscular injections of diphtheria antitoxin in large doses. The considerations that led to the employment of this treatment were:

First, that horses were not subject to sympathetic uveitis and hence their scrum might be antagonistic to the disease; second, that the serum of a horse immunized to diphtheria toxin probably contained enhanced nonspecific factors of immunity; third, that it was remotely possible that the antitoxin itself might be antagonistic to the disease; fourth, that the serum might act as an antianaphylactic in case the anaphylactic theory of the disease were true.

Since then this treatment has been carried out in thirty-one additional cases, most of them under the personal supervision of the senior writer. Three of these cases are excluded from consideration because they are of no significance as to the value of the treatment, since vision was reduced by the disease to light perception before the antitoxin was first administered. In none of these three cases was the exciting eye examined microscopically.

The diphtheria antitoxin was supplied by the Massachusetts State Board of Health, and in each case an attempt was made to follow the procedure outlined in the communication referred to:

The exciting eye is removed only if it is so badly injured that there is no reasonable chance that it will recover useful vision. The patient is tested for hypersensi-

tiveness to antitoxin, by injecting one drop intradermally. If there is no reaction within thirty minutes, the test is negative. If negative, 20,000 units of diphtheria antitoxin are heated to body temperature and injected subcutaneously or intramuscularly, preferably into the buttocks. If the test is positive, the patient is desensitized by injecting the antitoxin at intervals of fifteen minutes in divided doses, .1 c.c., .2 c.c., .5 c.c., 1 c.c., 1.5 c.c., 2 c.c., 2.5 c.c., and then the remainder of the 20,000 units. In the case of children the dose is reduced in proportion to body weight. The same dose is given daily for one week. If the case is an early one and the ocular congestion has subsided within this time, the injections are discontinued for one week, and then given at weekly intervals for two or three weeks. If the case is an advanced one, the daily injections are continued until marked improvement has taken place or the patient has developed severe symptoms of anaphylaxis. They are then given at weekly intervals, each time in divided doses. In cases with marked congestion, sodium salicylate is given in increasing doses but not to the limit of toleration. Locally, atropine is employed in the usual manner. If the pupil does not dilate fully, or if there is increase in tension, daily subconjunctival injections of adrenalin are given. If the tension remains over 28 mm. (Souter), iridectomy is done as soon as the eye otherwise shows marked improvement. If there is a pupillary membrane which reduces vision too greatly, and the eye has remained quiet for three months or longer, the lens is removed, the patient being kept under the influence of antitoxin by daily injections before and after operation.2

Including the previous seven cases, we

now have thirty-five consecutive cases upon which to base conclusions as to the effectiveness of the treatment. This series of cases is actually small, but is large relative to the frequency of the disease, and covers a period of about eleven years. The important facts regarding these cases are given in the accompanying table cases are not grouped in chronological order In twenty five cases which we shall term the "proved" cases, the diagnosis was confirmed by microscopic examination of the enucleated eye (22 cases) or a piece of iris obtained by iridectomy (3) cases) In seventeen of these proved cases useful vision resulted-in eleven it was 20/30 or better In Case 4 the resulting vision was only 20/100, in Case 9, 20/70, and in Case 12, 20/50, but in each of these cases this was not due to the disease but to semile cataract. In Case 15, one of the first cases in which the treatment was used, the resulting vision was only 20/70, but according to our present views the patient was given insufficient treatment In only five of these successful cases did the microscopic examination show that the sympathogenic uveitis was severe in the exciting eye. This fact indicates that in most of the successful cases the treatment was begun early, but affords no evidence that the uvertis would not have be come severe if iintreated

Of the eight proved cases in which the final vision was low or nil, vision was reduced to 4/200 or less in three before the treatment was begun In Case 18, after all inflammatory signs had subsided, the vision was 20/40 Then an attack of acute glaucoma reduced the vision to counting fingers The lens had become slightly cataractous and was removed without any recurrence of the uveitis A clear pupil was obtained, but the vision was only 4/200, evidently due to the attack of glaucoma In spite of this result, the bene ficial effect of the treatment in this case seemed obvious Nevertheless, we have not included it among the successful cases because the acute glaucoma probably resulted from the preceding uveitis

In five of the eight unsuccessful cases, there were recorded no reactions to the injections. This may explain the failure of the treatment. In seven of the unsuccessful cases the microscopic examination showed severe involvement of the exciting

eye, additional evidence that the sympathizing eye was severely involved at the beginning of treatment. In the other unsuccessful case the microscopic findings also indicated severe involvement considering the short time (one week) that symptoms had been manifest.

Of the ten cases in which the diagnosis was based upon the clinical evidence alone, excellent vision resulted in seven But in two of these, (Cases 26 and 32) in which vision is 20/20, the patients are still under treatment. In one case (33) of the severe plastic type, in which vision was reduced to 4/200 at the beginning of treatment, the inflammation subsided in one month with vision no worse, and the patient was then discharged. In two unproved cases (34 and 35) the treatment apparently failed, but in the latter the chief cause of loss of vision was secondary glaucona for which the patient refused operation and any further treatment Thus, excluding the two cases in which the patients are still under treatment, and the case followed only one month after the onset, the treatment was effective in five out of seven unproved cases Based upon the evidence of the proved cases alone, or upon that of the whole series, we can say that when antitoxin is begun at an early stage of the disease satisfactory vision will be obtained in at least two thirds of all cases of sympathetic uveitis. If we exclude three un successful cases (20, 21, and 25) in which the sympathizing eye was severely involved at the beginning of treatment, also Case 35 in which treatment was discontinued against advice, and include all others, we can say that satisfactory vision will be obtained in eighty per cent of all cases when the treatment is begun early

It seems probable that an anaphylactic reaction is advantageous if not essential to the effectiveness of the treatment, for recognizable reactions occurred in almost all the successful cases. Such reactions, however, do not necessarily ensure success, since of the ten unsuccessful cases in the whole series, they occurred in five, in three of which vision was fairly good at the outset. It is possible also that desen sitization of the patient, after becoming sensitized, was of importance. For whether the disease is due to allergy alone, or to infection, allergy may play

an important part in it, and it is possible that antiallergic factors may be of value even if not specific for the disease in question.

Exact notes as to the anaphylactic symptoms when the latter were slight were unfortunately not made in all of the cases. In one case (12) deltoid paralysis in one arm occurred which disappeared in about a year. Otherwise there were no serious effects of the treatment. One patient (Case 18) died of pernicious anemia $4\frac{1}{2}$ years after the last injection. This undoubtedly was simply a coincidence, since none of the other patients developed anemia. One patient (Case 25) had slight anaphylactic shock, which was relieved by injections of adrenalin. This no doubt could have been avoided by proper desensitization. Febrile reaction, and urticaria developed after about the fifth or seventh daily injection. The highest temperature was 104°. In a few patients there was arthritis for a few days. These symptoms were unpleasant but not alarming.

In seven cases iridectomy or combined cataract extraction was performed during the course of treatment or soon after subsidence of the inflammation, without causing exacerbation or recurrence of the inflammation. In three cases, however, (22, 23, and 24) operative interference probably contributed to the unsuccessful results. These three cases seem to indicate that unless the patient can be made sensitive to the antitoxin, and the treatment is obviously beneficial, no intraocular operation should be performed.

In this disease a distinction between exacerbations and recurrences is difficult to make. We know that the disease may become active again after many years (Case 17), suggesting that in many cases the lesions have never entirely healed in spite of absence of all clinical signs. From this point of view all clinical recurrences in this disease are really exacerbations. In our series, in most of the successful cases there were slight exacerbations before all inflammatory signs disappeared. In only one case (16) however, with the possible exception of two others, did inflammatory signs recur after the disease had apparently completely subsided under the treatment.

Case 16 is worthy of special considera-

tion because in spite of its mildness, slight exacerbations occurred eight times within eight years, and because of the histological picture in the exciting eye removed four years after the onset of the disease. The right eye sustained a perforating wound of the cornea with prolapse of the iris. Nine weeks later, the left eye showed slight ciliary congestion, and slight posterior synechia, but the vision was 20/20. The patient was given seven injections of his own whole blood, about fifteen c.c. each, over a period of about five weeks. At the end of this treatment, precipitates and Koeppe nodules persisted, and vision was 20/30, but there was no congestion. Three months after the onset, blurring of the optic disc was noted and the antitoxin treatment was begun. The posterior corneal precipitates became much less and the patient was discharged with vision of 20/20. Two months later an iridectomy was performed upon the injured eye without causing any exacerbation. The patient's father then learned to recognize the presence of precipitates on the cornea by viewing the eye in direct sunlight, and brought the patient to the hospital whenever he noted them. Each attack was treated with antitoxin. About four months after the first injection of antitoxin the patient developed asthmatic attacks at night. Four years after the onset of the disease the exciting eye, although it still had some vision, was removed in the hope of checking the exacerbations in the other After this there was an exacerbation about a year later, with vision reduced temporarily to 20/30. Recently after an interval of two years there was another exacerbation which through neglect was allowed to progress for four weeks without treatment. The iris had become tied down, there was congestion and abundant precipitates on the cornea, and the vision was reduced to 20/50. It was found that the patient had become insensitive to horse serum. Treatment was given, the patient again became sensitive, and the attack is subsiding, vision now being 20/20.

Microscopic examination of the eye removed four years after the onset showed a notable condition, namely typical foci of sympathetic uveitis with epithelioid and giant cells scattered throughout the choroid, but the interesting feature was that these foci were very small, and had not damaged the choroid sufficiently to affect vision. In fact the picture simulated that of an early sympathogenic uveitis. So far as we know, such an observation has not hitherto been made. Assuming that lesions of the same kind exist in the other eye, it is readily understandable why the vision of this eye has remained so good,

Case 32, one of the unproved cases,* promises to be similar to the foregoing. After the first treatment with antitoxin there was prompt subsidence of congestion in the sympathizing eye. There have been no posterior synechiae, and the vision has remained 20/20, but posterior corneal precipitates have persisted up to the present time, a period of nine months. In the exciting eye, slight congestion at the site of the wound and numerous precipitates have also persisted. The patient is very sensitive to horse serum.

To ascertain certainly the value of diphtheria antitoxin in the treatment of sympathetic uveitis it is necessary to know the final results in a series of proved cases in which this treatment has not been employed. In the literature we have been unable to obtain a series of cases suitable for comparison with ours. The cases either have been selected, or the final results are not recorded, or the diagnoses have not been confirmed by microscopic examination in number. Post3 has recently reported a series of cases in which the diagnoses were made microscopically. Various methods of treatment, not including the use of diphtheria antifoxin, were employed, and useful vision resulted in fifty-four per cent of twenty-four cases. However, Post does not state how long the patients were followed and gives no details by means of which we can estimate the results with sufficient accuracy. It is certainly difficult to believe that under ordinary treatment useful vision will be ultimately preserved in more than one-third of all cases of sympathetic uveitis, and we are convinced that at present the use of diphtheria antitoxin offers by far the best chance for success in the treatment of this disease.

ALLERGY IN ITS RELATION TO SYMPATHETIC OPHTHALMIA

ALAN C. Woods, M.D., Baltimore, Md.

From the Wilmer Ophthalmological Institute of the Johns Hopkins University and Hospital, Baltimore, Maryland

The purpose of this paper is to collect and present the existing evidence that allergy is a factor in the etiology of sympathetic ophthalmia. It is not my function to present or attack other theories concerning the actual cause of this disease, and only briefly need such other theories be mentioned that a general picture may be had of the conflicting viewpoints.

There are at present four widely different ideas on the etiology of sympathetic ophthalmia.

The first of these is that the disease is caused by some unknown and undiscovered organism with a specific predilection for uveal tissue. This organism is assumed to

gain entrance to the exciting eye at the time of the penetrating wound, and later through the blood stream or along the optic pathways to reach the second eye where it produces the characteristic clinical and pathologic picture. At one time or another the isolation of such organisms has been reported, but further investigations have not confirmed these reports. Samuels1 as a result of his studies on the distribution of the pathologic process throughout the uvea, supports the idea of the bacterial etiology of sympathetic ophthalmia, and believes the infecting bacteria gain entry at the site of the penetrating wound of the eye. However, the most painstaking and extensive bacteriologic investigations of both the exciting

References

^{*}Since this was written, two epithelial cysts that had developed in the anterior chamber of the exciting eye, and also a considerable amount of iris tissue, were removed. Microscopic examination shows typical foci of sympathogenic uveitis in the iris. The case, therefore, is now a "proved case,

and sympathizing eyes have been almost uniformly negative, and there is today no positive evidence that sympathetic ophthalmia is caused by bacterium.

The second idea is that sympathetic ophthalmia may be caused by a filterable virus. von Szily² was the first to investigate this question. That lesions may be produced in the eye by inoculation with herpetic and other filterable viruses is unquestioned, and undoubtedly these experimental lesions bear some resemblance to the pathologic picture of sympathetic ophthalmia. The crucial point, however, is: Can a filterable virus be isolated from either exciting or sympathizing eyes which will produce the characteristic or suggestive picture on reinoculation? Here the experiments are extensive, Gifford and Lucic,³ Leser,⁴ Marchesani,⁵ Undelt,⁶ and others having performed this experiment with different variations. The results have as a rule been negative, or, when suggestive, open to serious question by the investigators themselves. All that can be said now is that the idea is stimulating and suggestive, but barren of indication or positive proof.

The third theory is more specific. In its essence it expresses the idea that sympathetic ophthalmia is a tuberculous or tuberculotoxic disease. The idea originated in the close resemblance in the pathologic picture of sympathetic ophthalmia and ocular tuberculosis. It must, however, be remembered that Fuchs and other pathologists have pointed out definite differences. This theory has been supported by the investigations of Guillery,7 who inserted semipermeable capsules containing living tubercle bacilli between the ciliary body and sclera of the eyes of rabbits. The tuberculotoxin diffusing out from these capsules produced disease first in the inoculated eye and later in the second eye-lesions which Guillery believed to be identical with sympathetic ophthalmia. While these experiments found partial confirmation in the work of Kolen,8 Guillery's conclusions were contradicted by Poos and Sartorius,9 Meesman and Volmer,10 Marchesani,11 Kiyosawa,12 and others. Further support to the tuberculous etiology of sympathetic ophthalmia was given by the more recent studies of Meller.13 By means of the Lowenstein technic, he isolated tubercle bacilli from an exciting eye and from the blood stream of patients with sympathetic ophthalmia. On these findings, which Meller confirmed in several reported experiments, he bases his belief that sympathetic ophthalmia is essentially a tuberculous disease. For the moment giving credence to the reliability of the Lowenstein technic and Meller's reported findings, the immediate question is: How do these facts explain sympathetic ophthalmia?

His explanation for the disease in the exciting eye is quite logical. The wound in the exciting eye, with consequent opening of the blood vessels, precipitates the localization of tubercle bacilli in the injured eye. These bacilli then produce the characteristic picture of sympathetic ophthalmia in the exciting eye, which in Meller's opinion is really a proliferating tuberculous uveitis. Meller's¹⁴ explanation for the outbreak of the disease in the second eye is not so clear. He speaks of the "influence exerted upon sensitivity by the decomposition of tissue." of the fact that proliferating cell growths may break in the choroidal veins and cause new deposits of germs, and of the possible biological affinity of the tubercle bacilli for uveal tissue, due to their growth in the injured eye. Lowenstein¹⁵ speaks of this elective organotropism of tubercle bacilli with a little doubt, but emphasizes the fact that tuberculosis of one kidney apparently predisposes the second kidney to similar disease. He notes this same fact in bone tuberculosis. He suggests that the degenerating cells at the site of the original metastasis (i.e. the exciting eye) become foreign bodies and act as antigens. The absorption of these highly specific antibodies, "choroidal resorbins," injure the second eye in such manner that when the tubercle bacilli circulating in the blood stream finally reach this ground prepared by the resorbins, they are able to germinate, and thus in the sympathizing eye produce the picture of sympathetic ophthalmia.

Meller's views have met with both support and criticism. They have been supported by Purtscher,16 Sallmann,17 Nagayama,18 and others. They have likewise been severely criticized by numerous investigators. Tess¹⁰ is frankly skeptical of the dependability of the entire Lowenstein technic. Experiments by de Andrade²⁰ on the influence of ocular injuries on the localization of circulating tubercle bacilli in the eye are certainly not convincing. Nagayama was unable to isolate tubercle bacilli from an enucleated exciting eye. Riehm²¹ seriously questions and challenges the entire assumption. von Hippel22 has carefully studied the question, using the Lowenstein technic for a period of two and a half years. His careful analysis does not support Meller's views. For example, the blood of eleven patients with penetrating wounds of the uveal tract was examined by the Lowenstein technic. Eight cultures were negative and three positive. None of the three positive patients developed sympathetic ophthalmia. Gilbert,23

Krasso,24 and Raverdino25 have also criticized Meller's views adversely.

Thus stands the situation of sympathetic ophthalmia as a tuberculotoxic or tuberculous disease. Guillery's experiments are interesting, but it does not appear that he was dealing with a true experimental sympathetic ophthalmia. Meller's conviction that sympathetic ophthalmia is a tuberculous disease must be judged first on the reliability of the Lowenstein technic. This cannot yet be fully accepted. Even if true, to explain the localization of the tubercle bacilli in the sympathizing eye, the proponents of this theory must assume some other predisposing influence. To supply this gap, they fall back on the assumption of an allergic factor, or at least something closely akin to it.

The fourth idea is that allergy is concerned in the etiology of the disease. This idea first found expression in 1910 when the tremendous importance of allergy and immunity in the causation of disease was gradually being realized. This theory commanded attention because it explained the variable incubation period between the injury to the exciting eve and the outbreak of the disease in the sympathizing eye, and likewise explained the uniformly negative bacteriologic investigations. The theory was first advanced by Elschnig,26 and has been modified by various later investigators. The essence of this theory is that the original penetrating wound allows the absorption of some antigen which produces a sensitization of the injured eye, and later of the sympathizing eye. Sympathetic ophthalmia may be the result of an allergic intoxication from further absorption of the same antigen, or such sensitization and intoxication may permit some unknown, possibly quite unspecific, factor to produce the characteristic clinical and pathologic picture of the disease. Elsching originally believed uveal pigment to be the protein responsible for such sensitization and intoxication, and presented certain experimental evidence to support this view. On the other hand, Marchesani27 apparently believes that nonspecific bacterial protein absorbed from the eye produces a paired-organ sensitivity of the two eyes, and not in other tissues. This developing sensitivity in the second eye makes possible the localization of the bacterium in the second eye. Riehm²⁹ reported experiments indicating that foreign protein absorbed from one eye produces an elective sensitivity of the second eye, and believes that similar organs with a common trophonervous influence are a closed entity with a common inflammatory reaction, which should be designated as elective sensitization, rather than sympathetic disease. On this basis he argues that sympathetic ophthalmia may be due to various etiological factors, acting through elective sensitization in this closed entity of paired organs. Other authors have expressed somewhat similar opinions—variations of the allergic theory.

With these latter experiments and views I have had no experience. If uveal pigment, acting as a foreign protein, can produce a sensitization of the second eye, it appears quite probable that other foreign proteins may do likewise. Yet the idea of a "closed entity" and "elective sensitization" in the immunological sense is difficult to follow, and the experiments along these lines and the conclusions drawn from them appear open to obvious criticism. However, the idea that a native tissue protein, such as uveal pigment, may produce sensitization is open to immediate criticism, assuming as it does the "Horror Autotoxicus," stressed years ago by Ehrlich. Such an idea must be submitted to rigid scrutiny, and the evidence in favor of it thoroughly investigated and examined, before it can be given place and recognition in modern medicine.

What is the evidence in favor of allergy to uveal pigment being concerned in the etiology of sympathetic ophthalmia? To my mind the evidence may be arranged under three headings—experimental, clinical, and pathological. These three phases of the problem it is the purpose of this paper to sum-

marize and report.

Experimental Evidence

Elschnig's original theory assumed that sympathetic ophthalmia was an anaphylactic phenomenon produced through sensitization of the organism, especially the fellow eye, by absorption of the disintegrating uveal tissue in the exciting eye. Further absorption, after sensitization had taken place, produced intoxication, manifested in the second eye as sympathetic ophthalmia—a mechanism similar to that assumed by von Pirquet to explain serum sickness.

To give the semblance of plausibility to such a theory, it must be demonstrated that uveal tissue possesses antigenic properties in the host, and it was on this point that Elschnig's original researches centered.²⁰ Different series of rabbits were immunized by the repeated injection of foreign uveal tissue, of homologous (rabbits) uveal tissue, and finally of uveal pigment, isolated from the uveal tract, purified by precipitation with ammonium sulphate and repeatedly washed. The serums of these

animals were then examined in the complement fixation reaction against all the various antigens used for immunization, and also against antigens of liver and kidney tissue obtained from animals of the same species whence the uveal tissue had been derived. By these experiments Elschnig determined the immunological properties of uveal tissue and uveal pigment, as shown by complement fixation. He found that uveal tissue was capable of acting as an antigen, not only in other species of animals, but also in the same species from which the uveal tissue had been derived, that it was organ-specific in its reactions and not species-specific, and that the pigment of the uveal tract was the constituent responsible for these strange properties. To express it less technically, uveal pigment is a similar protein in all species of animals. Immunologically it differs from the other body protein and is capable of acting as a foreign protein in animals of the same species. These findings were confirmed by Weichardt and Kummel,30 who used the epiphanin reaction. They were questioned by Rados,31 Fuchs and Meller,32 and von Szily,33 who attacked the problem from a different approach—chiefly by anaphylactic experiments in guinea pigs. However, on the basis of this fundamental observation, Elschnig based his original anaphylactic theory of the etiology of sympathetic ophthalmia.

These complement fixation studies were repeated in their entirety in 1916 in the Department of Research Medicine of the University of Pennsylvania;34 and with the exception of the complete absence of species-specificity, a relatively unimportant point, Elschnig's original findings were confirmed. These studies were again repeated and confirmed by Nakamura.35 In the elaboration of the problem, it was then necessary to confirm these peculiar immunological properties by methods than the complement fixation reaction. The studies of Rados, Fuchs and Meller, and von Szily with anaphylactic experiments had been negative. The epiphanin reaction used by Weichardt and Kummel was of somewhat less than doubtful value, and the nature of the pigment antigen did not lend itself to the precipitin reaction. To supply the necessary confirmation, the antigenic properties of uveal tissue and uveal pigment were studied by perfusion of the eyes

of properly sensitized dogs.

Primarily,36 it was demonstrated that when the eyes of an animal; sensitized by the injection of a foreign protein, were perfused with a fluid containing the specific antigen, there occurred a marked contraction of the pupil—essentially a Dale-Schultz phenomenon, the contraction of sensitized smooth muscle in the presence of the specific antigen. Dogs were then sensitized to both heterologous and homologous uveal tissue and uveal pigment, and their eyes later perfused with defibrinated blood, to which was added in different experiments, the various anti-The general scheme of this perfusion is shown in Fig. 1. Again as a result of these experiments,37 the same antigenic properties of uveal pigment—organspecificity, partial lack of species-specificity, and the ability to act as an antigen in the homologous animal—were again demonstrated.

This demonstration that uveal tissue could act as an antigen in the homologous animal was the first link in the chain of evidence that allergy might be concerned in the etiology of sympathetic ophthalmia. The next steps were to demonstrate first that inflammatory allergic reactions could be produced in the uveal tract of an eye by the antigenic action of uveal pigment and, secondly, to produce sympathetic ophthalmia experimentally by such a mechanism. The first point has been successfully demonstrated; the second has not.

The experiments demonstrating that an inflammatory allergic reaction could be produced in the uveal tract of the eye by the antigenic action of uveal pigment were as follows³⁸:

Twelve normal dogs were given a sensitizing injection of 1 c.c. of uveal pigment emulsion by vitreous injection. A traumatic iridocyclitis in the injected eye followed the sensitizing intraocular injection. One dog developed a secondary infection and was discarded. After a period of from two to three weeks these dogs were given injections of phloridzin or uranium nitrate to produce an underlying disturbance, a phloridzin glycosuria or a uranium nephritis, and thus to lower their resistance. They were all then given an intoxicating injection of eight c.c. of uveal pigment emulsion by intraperitoneal injection. After the intoxicating dose

there followed a definite exacerbation of the traumatic iridocyclitis in the injected eye, and three of the ten experimental dogs developed a marked iridocyclitis in the second uninjected eye. Pathologically, these second eyes showed round cell infiltration of the anterior uvea, the iris, and ciliary body, with extension of the mononuclear infiltration up along the pectinate ligament to Descemet's membrane. No epithelioid or giant cells were found. It was believed at that time that this process was undoubtedly an anaphylactic or allergic reaction in the sensitized eyes, and might well represent sympathetic ophthalmia in the dog.

The weak points in this experiment are, however, apparent. All of the dogs showing the ocular reaction in the second eye were ill with a glycosuria or a nephritis, and on autopsy two of them showed an advanced bronchopneumonia. It may be that the lowering of resistance by these secondary infections was the necessary element to permit the outbreak of the eye inflammation, yet it must be admitted that this complicating element detracts from the force of the experiment. Further, it was assumed that the primary injection in the eye had produced a sensitivity in these animals, but this assumed sensitivity was not demonstrated by skin tests with pigment, or by biopsy of the

excised skin. In the second experiments ten normal dogs were subjected to an operative insult on the uvea of the right eye, with operative incarceration of the ciliary body in the wound. One dog was discarded on account of secondary infection, and a second dog was accidentally killed. The remaining eight dogs were not given phloridzin, uranium nitrate, or any other substances calculated to produce an underlying disturbance. They were later given intoxicating intraperitoneal injections of uveal pigment. Six dogs, which had all developed positive complement fixation reactions in the blood serum to uveal pigment antigen, showed no reaction of any kind to the intoxicating injection. The re-maining two dogs, who had not developed positive complement fixation tests to uveal pigment antigen, showed an exacerbation of the postoperative reaction in the operated eye, and a definite iridocyclitis in the unoperated eye. Pathological examination of these eyes showed the same picture already mentioned-a mononuclear infiltration of the ciliary body and root of the iris, with extension of the inflammatory process up along the pectinate ligament to Descemet's membrane. The general necropsy on one of the dogs, the one showing the maximum octilar reactions, was entirely negative. The second dog showed patches of bronchopneumonia. Again this experiment may be criticized for the reason that the hypersensitivity to uveal pignient was assumed and not proven by skin tests or by biopsy.

These experiments, however, appear to demonstrate that by sensitization and intoxication with uveal pigment, an allergic iridocyclitis can be produced. It is possible that the disturbance in the second uninjected and unoperated eye is the canine manifestation of sympathetic ophthalmia, but until we can produce the characteristic picture observed in the human, and demonstrate skin hypersensitivity to pigment, both clinically and by biopsy, and in experimental eyes produce the picture of epithelioid and giant cell infiltration with pigment phagocytosis, this cannot be granted.

In experiments underway at present we are endeavoring to produce demonstrable pigment hypersensitivity in dogs. My colleague, Dr. E. L. Burky, has recently found that by the simultaneous injection of a highly potent staphylococcus toxin and lens protein intracutaneously, he could produce a high degree of hypersensitivity to lens protein in rabbits. Without the intermediate use of the staphylococcus toxin, the injection of lens protein produced only a high precipitin titre, and did not produce sensitivity. We therefore, in a preliminary experiment, gave two dogs sixteen intraperitoneal injections of pigment and toxin, and two control dogs intraperitoneal injections of pigment alone. At the end of two months these dogs were skin-tested with uveal pigment. The dogs receiving the pigment-toxin mixture gave doubtfully negative clinical skin tests. The microscopic examination of the excised skin, an examination which will later be more fully described, was negative in one dog and doubtful in the second dog. The dogs receiving pigment alone gave completely negative skin tests, both clinically and microscopically. All four of these dogs were then subjected to a similar operative procedure on the right eye. A conjunctival flap was made, the sclera was incised over the ciliary body, a sharp hook was inserted, and the ciliary region was freely traumatized. Two tenths of a c.c. of uveal pigment emulsion was then injected in the traumatized uvea. The two control dogs, receiving pigment alone, gave little reaction to this operation, the eyes quickly recovering in four days. The two dogs

receiving the pigment-toxin injections both showed a prolonged chronic uveitis for over a month. At the end of this period the dogs were again skin-tested, and again were doubtfully negative. The general clinical appearance was that of an indolent progressive uveitis. One dog showed a definite nodule in the iris. Efforts to produce a disturbance in the second eye were fruitless. One month after the operation on the right eye, the dogs were given a carotid injection of one c.c. of uveal pigment, without any effect on the left eye. One week later they were given an intraocular injection of pigment in the left eye, again without effect. Apparently the combination of traumatization with injection of pigment was necessary to produce the clinical picture of a chronic uveitis. Unfortunately, these dogs were lost through accident, and there is no pathological material available for study. The experiment is now being repeated with a larger number of animals.

Clinical Evidence

Does uveal pigment produce any immunological reaction in man after wounds of the uveal tract which would permit its absorption? This question has been investigated by two methods: first, by examining in complement fixation reaction against an antigen of uveal pigment, the blood serums of patients who have suffered wounds and diseases of the uveal

tract; secondly, by studying the hypersensitivity to uveal pigment shown by an intracutaneous test in similar patients.

The essential finding in the first study³⁹ was that when normal healing of the injured eye occurred, there were complement binding antibodies to a pigment antigen in the blood stream. When either a persistent traumatic uveitis or sympathetic ophthalmia followed the initial uveal wound, such complement binding antibodies were absent. The other observations were unimportant. There was apparently no absorption of pigment in constitutional uveitis, the complement binding antibodies being absent regardless of the outcome of the disease; in pig-

mentary degeneration of the retina, the complement binding antibodies were present in a low degree, no reason for this being apparent. (See Table I.)

These studies, when done in 1921, were interpreted on the basis that the presence of such pigment antibodies in the blood stream was an evidence of protection of the fixed cells against intoxication by the foreign protein action of uveal pigment. In persistent traumatic cyclitis and in sympathetic ophthalmia these protective antibodies did not occur, and therefore these patients were both deprived of the beneficial action of these antibodies, and the fixed cells, if sensitized by the primary absorption of uveal pigment, were exposed to intoxication by further absorption. Should an allergic reaction develop in the second eye, the clinical picture would be that of sympathetic ophthalmia.

This explanation was at that time logical and fitted in with the generally prevailing opinion that circulating antibodies were an evidence of vigorous response of the cells to foreign protein, and gave an immunity of the fixed cells to the foreign protein. Since then experimental observations of many types have made this view untenable. We know now that an individual or an experimental animal may show circulating antibodies in the blood stream and the fixed cells may be extremely hypersensitive to the specific foreign protein, and capable of anaphylactic shock or allergic reactions on subsequent absorption of the protein in question. Therefore, while it is possible that the interpretation of these studies first offered may be correct as far as uveal pigment is concerned, it is certainly wiser in the light of our present knowledge, to interpret these results more conservatively. Suffice it to say now, these studies at least indicate that in patients with wounds of the uveal tract, where normal healing occurs, there is definite evidence of absorption of pigment from the injured eye and of the production of an immune reaction to the pigment. This immune reaction is manifested by the occurrence of complement fixing bodies in the blood stream.

On account of the technical difficulties of the complement fixation reaction and the instability of the pigment antigen used in the test, this method of investigation was abandoned as a clinical diagnostic aid, and a second method of investigation—the determination of the presence or absence of hypersensitivity to pigment by an intracutaneous test with uveal pigment—was pursued.

The results of the intracutaneous tests are shown in Table II. They were reported first in 1932.40 Since then additional cases have been added, without any significant changes in the results. Positive pigment tests, indicating a systemic hypersensitivity, were found in a few cases of prolonged, noninfectious, recurrent, postoperative or posttraumatic uveitis. The histologic picture of such of these eyes as were enucleated was not that of sympathetic ophthalmia, but was somewhat suggestive. On the basis of these patients the suggestion was advanced that they were a hitherto undescribed clinical entity, an allergic endophthalmitis dependent on pigment allergy. To this view we still subscribe.

In all other forms of uveitis, excluding sympathetic ophthalmia, the intracutancous tests were entirely negative, with four exceptions. Three of these exceptions were doubtfully positive and might well have been classed as negative. No confirmatory biopsy of the excised skin was done on these patients. The fourth is the one clearcut "false positive." The patient was a nine year old boy, who after a repair operation recovered uneventfully penetrating corneal wound, from a through which the iris tissue had prolapsed. Two weeks after the injury he developed a strongly positive intracutaneous pigment test, which was later confirmed by biopsy of the excised skin. The test was later repeated with identical results. This patient has never developed any further ocular disturbance. Further reference will be made to this "false positive.'

All the patients with active sympathetic ophthalmia, twenty-two in number, gave positive reactions to the intracutaneous injection of uveal pigment. Two patients with old, inactive sympathetic disease, quiescent for years, in whom any pre-existing hypersensitivity might well be expected to have died out, gave negative reactions. While the great majority of the twenty-two patients giving positive reactions were positive on the first and

on repeated tests, this was not uniform. Several patients were encountered who were negative on the first test, only later becoming positive, and a few other patients were encountered who showed definite fluctuations in their hypersensitivity. While there may exist negative phases in the sensitivity during the active ment. The cutaneous hypersensitivity to uveal pigment is observed predominatingly in sympathetic ophthalmia, but is also observed in a few patients who show only a protracted, noninfectious, posttraumatic or postoperative uveitis.

The last clinical point deals with the therapeutic use of uveal pigment in sym-

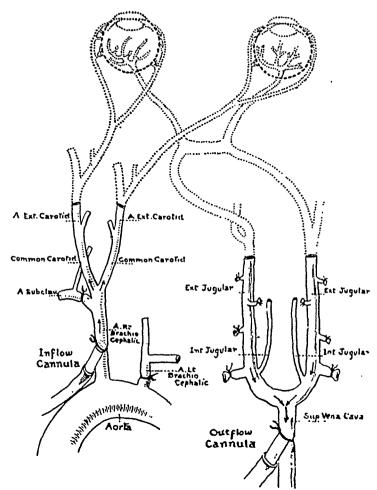

Fig. 1. Diagram showing position of inflow and outflow of the canulas and scheme of perfusion of the eye.

periods of the disease, hypersensitivity to uveal pigment is the general rule in patients with sympathetic ophthalmia.

On the basis of the above studies, the question "Does uveal pigment produce any immunological reaction in man after wounds of the uveal tract which permit its absorption?" may now be answered in the affirmative. The evidences of such reactions are the occurrence of complement fixing antibodies in the blood serum and a skin hypersensitivity to uveal pig-

pathetic ophthalmia. This treatment is based on the conception that allergy to pigment is at least a fundamental factor in the etiology complex, for it has been uniformly present in all cases of sympathetic ophthalmia with the exception of old, burned-out cases. Theoretically we should be able to remove this factor by desensitization with the specific allergin -an antigen of uveal pigment. What have been the results of such treatment?

To date twenty-three patients have been

treated by this procedure, two of whom disappeared while under treatment, and on whom no final information is avail able Light of the remaining twenty-one patients were blind when first seen and were treated only to control the inflammation. In four of these this was successfully accomplished, but in four others, on the last information, the inflammation was still active. Nine of the remaining thirteen patients showed complete healing of the sympathetic inflammation, with resulting vision from 20/15 to 20/200 The degree of vision resulting was usually dependent on the stage of the disease at which the therapy was instituted. The patients in whom the therapy was begun early in the disease obtained the best visual results, while the patients in whom the disease was more advanced, with consequent organic damage to the eye, pre served proportionately less vision with the subsidence of the infirmmation. One of these nine healed patients subsequently lost the eye through a second accident The remaining four patients, in whom the treatment was begun in the advanced stages of the disease, went steadily down hill to complete blindness. These results are shown in Table III

Summarizing these results, in nine of the thirteen patients in whom there was some hope of preserving vision desen stitzation with uverl pigment has been followed by complete subsidence of the sympathetic inflammation with preservation of useful vision, while in four patients the treatment was unsuccessful In eight patients, already blind when first seen, desensitization with pigment apparently controlled the inflammation in four in stances while in four instances it was insuccessful

Dr Jonas Friedenwald has attacked the question of desensitization from another angle Impressed by the undeniable facts that uveal pigment is an insoluble and feeble antigen and that absorption by parenteral injection must be relatively slow, he sought to obtain more rapid desensitization by producing a proliferation of the melanophores of the skin so the body might be provided with a readily available and widely distributed supply of pigment antigen, and desensitization might therefore be more readily achieved. To this end he treated three sympathetic

ophthalmia patients with ultraviolet light, exposing their bodies to an erythema dose three times weekly. Two patients, both children, made complete recoveries to normal vision, and in the third patient, an elderly semile individual, the sympathetic inflammatory process subsided, but vision was lost through organic changes in the eyes.

How do these results compare with re sults obtained by other methods of treatment? The results reported in the literature are confused by so many extraneous factors that it is almost impossible to judge. The disease is comparatively rare and the diagnosis in many reported cases is questionable. The stage of the disease in which treatment is instituted must influence the result, and but few authors report their complete experience with the disease The report of Post shows that of twenty five cases confirmed by pathologic diagnosis thirteen, or fifty-two percent, had recovery to normal vision. These were presumably all early cases. This record was achieved by no specific treatment, the patients receiving only the usual orthodox therapy Verhoeff, in a much larger series of sympathetic ophthal min patients reports sixty-six percent successful results by treatment with diplitheria antitoxin. In contrast to these records the patients treated by pigment desensitization in whom there was some hope for the preservation of vision, showed seventy percent favorable out

The question of the absorption of the insoluble pigment antigen has been studied recently by Dr H C Henton in the laboratory of the Wilmer Institute Henton has been able to demonstrate a high phagocytic index in patients treated with

pigment. Using the classical method of determining the phagocytic index, with the serum of the treated patient, and the washed cells of a normal individual, he has been able to demonstrate that the neutrophiles, under the influence of the serum of a treated patient, will take up as many as seventy pigment granules, against a normal maximum phagocytosis of about five granules, where a normal

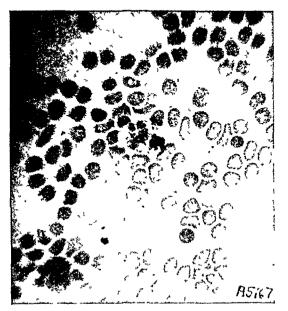

Fig. 2. Negative influence of normal serum on phagocytosis of pigment.

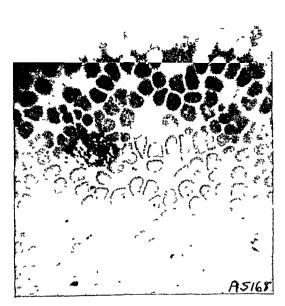

Fig. 3. Influence of serum of treated patient on phagocytosis of pigment (beef).

serum is used. (Figs. 2, 3, and 4). Further, he has been able to demonstrate that this phagocytosis of pigment is not specific for the type of pigment with which the patient has been treated. Thus the serum of a patient treated with bovine pigment will stimulate phagocytosis of bovine pigment, swine pigment and human pigment—a further demonstration of the organ-specific properties of uveal pigment.

The experimental and clinical evidence that allergy is concerned in the etiology of sympathetic ophthalmia consists, therefore, in the demonstration of the organspecific properties of uveal pigment, the ability of uveal pigment to act as an antigen in the homologous animal; the production of inflammatory lesions of the uveal tract by sensitization and intoxication with a pigment antigen; the demonstration of immune reactions in patients who have suffered penetrating wounds of the eye involving the uveal tract; the presence of hypersensitivity to uveal pigment in sympathetic ophthalmia, and the effects of pigment therapy in the disease.

Two radically different interpretations may be placed on this evidence. The first interpretation is that this evidence presents a logical and orderly sequence and indicates that allergy is concerned in the etiology of sympathetic ophthalmia. The second interpretation is that, granting the organ-specific properties and antigenic

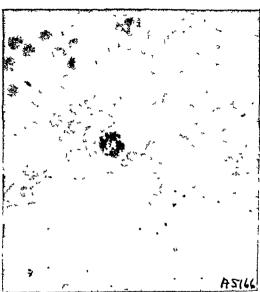

Fig. 4. Influence of serum of treated patient on phagocytosis of pigment (swine).

action of uveal pigment, nevertheless the immune reactions to pigment observed in patients are only the natural results of absorption of such a foreign protein, and are in no way related etiologically to sympathetic ophthalmia. Further, the beneficial effects of uveal pigment are not especially striking, and should only be regarded as a general nonspecific reaction.

To meet the points raised by this second interpretation, it must be demonstrated that pathological phenomena of pigment allergy and sympathetic ophthalmia are not unrelated entities but are similar, and that the histologic picture of pigment allergy is an essential part of the pathologic picture of sympathetic ophthalmia. To demonstrate this point we must turn to a study of the pathology of these two conditions.

Pathologic Evidence

This subject has recently been studied by Dr. Jonas S. Friedenwald.⁴¹ He first calls attention to the influence of allergy in pathology. This is especially evident in tuberculous infection where the entire histologic picture from inflammation, cascation and necrosis on the one hand, to little more than an inert foreign body reaction on the other hand, is governed by the presence or absence of allergy to tuberculoprotein.

In sympathetic ophthalmia, according to Koch's first postulate, one should regularly find the exciting agent present in the lesions. Therefore, if we assume that a reaction of the host to uveal pigment is concerned in the disease, we should expect to find pigment granules within the phagocytic cells in the lesions. In sympathetic ophthalmia this is precisely what we do find. The epithelioid and giant cells in the center of the lesions are loaded with pigment granules. (Figs. 5 & 6). It is true that pigment phagocytosis also occurs in other diseases of the eye, and Friedenwald has recently encountered a case of syphilitic uveitis when this was present to a marked degree. Yet it is in sympathetic disease that this phenomenon is constant and most marked, and constitutes the predominant characteristic. Even in the episcleral inflammatory nodules of sympathetic ophthalmia, this phenomenon of pigment phagocytosis is marked. Likewise, in such cases of sympathetic ophthalmia where there are deposits of pigment in the retina, the pigment is engulfed by the epithelioid cells. In contrast, in ocular tuberculosis, pigment phagocytosis is usually absent in the entire picture or, if present, is seen in conjunction with cascation and destructive lesions, and this is concerned chiefly with the monocytes.

Impressed by the massive cellular reaction, and the minimum vascular reaction in the picture of sympathetic ophthalmia, it occurred to Friedenwald that actual allergy to pigment in the skin might better be detected by studying the cellular reaction in the skin injected with uveal pigment rather than by relying on the slight vascular reaction about the site of injection as the index for a positive test. He also argued that if the allergy to uveal pigment is concerned in sympathetic ophthalmia, to fulfill Koch's second postulate, the injection of uveal pigment in the hypersensitive tissue should produce the characteristic picture of the disease. The experiment which would conclusively prove the relationship of pigment allergy to sympathetic ophthalmia would be the injection of uveal pigment in the unaffected eye of an individual hypersensitive to pigment; namely, such individuals as have shown a prolonged postoperative or posttraumatic uveitis without sympathetic onhthalmia, but with a demonstrable hypersensitivity to pigment, or in the "false positive" child already mentioned. This injection of pigment in human eyes being manifestly impossible, Friedenwald turned to the histologic examination of the skin injected with uveal pigment, secking to determine first, whether positive reactions to pigment could be better detected by histologic examination; and, second, to determine whether the injection of pigment in the skin of hypersensitive individuals produced in any way a pathologic picture comparable to that of sympathetic ophthalmia.

Primarily, it was necessary to discover the time, after the injection of pigment, at which any skin lesions due to pigment allergy would develop the maximum intensity. Accordingly, a patient suffering from sympathetic ophthalmia and clinically hypersensitive to uveal pigment, was given multiple intracutaneous injections of pigment, and the skin thus injected

was excised one, two, seven, and fourteen days after the injection and compared to similarly injected skin from normal controls, clinically insensitive to pigment.

78

Definite differences were observable at the end of seven days, and at the end of fourteen days the differences were pronounced. In the routine study which has

Fig. 5. Sympathetic ophthalmia—exciting eye Epithelioid cellnodules, giant cells, and mononuclear infiltration.

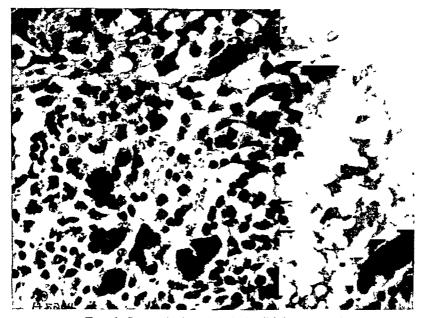

Fig 6 Sympathetic ophthalmia (high power of Fig 5) showing pigment phagocytosis

There was no difference in the histologic picture of the skin of normal and hypersensitive individuals when the skin was excised one or two days after injection. since then been carried out, the skin injected with uveal pigment has been excised at the end of fourteen days and examined histologically.

The skin of normal insensitive individuals shows uniformly large masses of unphagocytosed pigment surrounded by a zone of large mononuclears filled with

The skin of patients hypersensitive to uveal pigment shows a radically different picture. There is little or no unphagocytosed pigment. The whole area is in-

pigment granules. Beyond this is a narrow zone of lymphocytes, and beyond this, normal tissue without reaction of any kind. (Figs. 7 & 8—high and low power).

filtrated with epithelioid and giant cells full of phagocytosed granules. There are definite nodules and nests of epithelioid cells, surrounded by a zone of lymphocytes with perivascular round cell infiltration—a picture in its histologic appearance indistinguishable from sympathetic ophthalmia. (Figs. 9 & 10). logic examinations are read as either positive or negative. The criteria for a "positive" test are that all the injected pigment be phagocytosed and that there

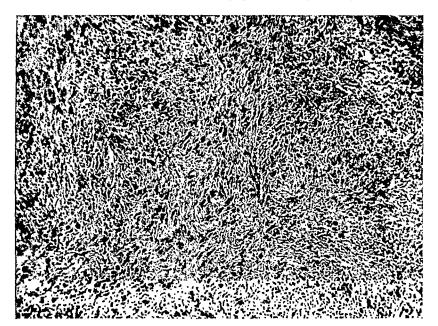

Fig. 9. Positive skin test. Epithelioid cells, giant cells, and pigment phagocytosis. Reaction covers about eight low power fields.

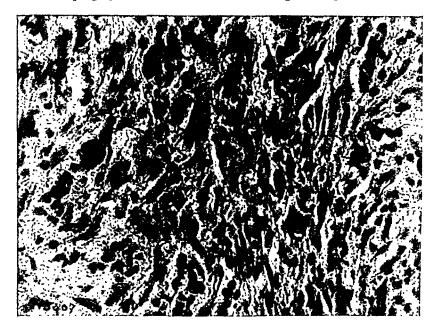

Fig. 10. Positive skin test (high power). Pigment phagocytosis.

To date there has been examined histologically the injected skin of thirty individuals, normal controls and patients with uveitis of various types. These histobe an abundant epithelioid cell reaction. The "negatives" are obviously those in which the pigment is not phagocytosed, and there is no, or only a slight, epi-

thehold cell reaction. In certain instances an intermediate reaction was observed where there was partial phagocytosis of pigment and moderate epithelioid cell mfiltration. In one instance, when the pigment phagocytosis was almost com plete, and the epithehoid cell reaction was marked, the test was read as positive, otherwise these slightly suggestive reactions are classed as negative. In four instances, when the injected skin was sent from other clinics for section and study, we have been unable to obtain a report on the chinical reading of the test . This leaves twenty-six individuals on whom intracutaneous pigment tests have been done, and on whom we have first independent clinical readings of the tests as positive or negative, and later histologic examinations with similar classifications as positive or negative reactions The results of this study are shown in Table IV

Five patients showed a positive clinical intracutaneous test, and each of these was later read as positive on histologic examination by a pathologist (Dr Friedenwald) In one of these specimens, the phagocytosis of the pigment was marked, but not complete, however, the epithehoid cell reaction was extreme Twenty tests were read as negative clinically, and all were classed as negative on histologic examination. One test was read as a doubtful chincally, and was read as negative by Dr Friedenwald This patient is interesting in that he was believed on clinical examination to have sympathetic ophthalma, but made an uneventful recovery without enucleation of the supposedly exciting eye This clinical diagnosis is therefore open to question This study shows clearly the close correlation of the clinical and histological reports However, the tests are at times difficult to read clinically, and there is a personal element involved It is obvious that greater reliance should be placed on the histologic picture of the excised skin

The second question is What is the relation of the histologic examinations, read as positive or negative, to the clinical ophthalmological picture? This relationship is shown in Table V

Seven patients with sympathetic ophthalmia all showed positive histologic skin reactions to uveal pigment. In six instances the phagocytosis of pigment was complete and the cellular reaction marked and extensive In the seventh instance there was still a small amount of unphagocytosed pigment, but the epithelioid cell reaction was again extensive and marked, and the test was read as positive In the uveitis group, without sympathetic ophthalmia, thirteen showed negative skin tests on histologic examination, and one a positive reaction This positive reaction occurred in the "false positive" child already described Four normal individuals gave entirely negative skin tests on histologic examination These studies confirm those found on the clinical reading of the intracutaneous pigment test, and indicate the constant presence of pigment allergy sympathetic ophthalmia, and its comparative rarity in other conditions Further. they clearly show the exact similarity of the histologic picture of pigment allergy and sympathetic ophthalmia

Comment

Such is the evidence that allergy is concerned in the etiology of sympathetic ophthalma. Briefly summarizing the points we have presented, the evidence consists in the demonstration of the organispecific properties of tiveal pigment, the ability of useal pigment to act as an

antigen in the homologous animal, the production of an experimental uveal inflammation through the use of uveal pigment as an antigen, the demonstration of immune reactions to pigment in patients who have suffered injuries which permit the absorption of uveal pigment, the partial control of these observations in experimental animals, the occurrence of hypersensitivity to pigment in certain cases of posttraumatic and postoperative uveitis, the constant occurrence of pigment allergy in patients with sympathetic ophthalmia, the results obtained in the treatment of sympathetic ophthalmia by desensitization with pigment, the phagocytosis of pigment in the pathologic picture of sympathetic ophthalmia, and the exact similarity of the histologic pictures of pigment allergy and sympathetic ophthalmia.

This appears to be a convincing array of evidence, but does it indicate that pigment allergy is the actual and only cause of sympathetic ophthalmia? We must remember that we have found pigment allergy in certain cases of noninfectious, posttraumatic, and postoperative uveitis without sympathetic disease, and in one case where there was uneventful healing of the uveal wound with neither posttraumatic uveitis or sympathetic ophthalmia—one case only, but so clearcut it cannot be overlooked. Remembering this we must answer this question in the negative; the evidence does not indicate that pigment allergy is the actual and only cause of sympathetic ophthalmia. The evidence does indicate that pigment allergy is the predisposing factor necessary for the outbreak of sympathetic disease. In short, it lays the necessary foundation for the disease to occur, and apparently determines the pathologic picture. But when the proper foundation is laid, and the development of pigment allergy sets the stage for the development of sympathetic ophthalmia, what factor initiates the inflammatory process?

On this point we can only speculate.

Friedenwald offers the ingenious suggestion that the proliferation of melanophores in the Dalen-Fuchs nodules may be the factor. He suggests that while the melanin in the normal cells produces no reaction in the sensitized tissue, that the proliferating melanophores in the Dalen-Fuchs nodules are especially susceptible, that they are vulnerable to the tissue antibodies, and undergoing autolysis, release their pigment which elicits the allergic inflammatory process. This hypothesis is based on the observation that in sympathetic ophthalmia the melanophores in the Dalen-Fuchs nodules have undergone autolysis, and their pigment is phagocytosed by the epithelioid and giant cells. But is this the cause or the result of the sympathetic disturbance? The question cannot be answered. It may be that any nonspecific stimulus, bacterial or toxic, may be the initiating factor once the stage is set by the development of pigment allergy. It may be that pigment allergy in such eyes predisposes them to the deposition of tubercle bacilli from the blood stream-in line with Meller's views that tubercle bacilli are the actual cause of sympathetic ophthalmia. We do not know. None of these ideas are completely convincing. The question must be answered by first producing in experimental animals the same picture of pigment allergy, with the same positive skin reactions to uveal pigment we observe in the human. When this is accomplished, we can then study the effects of various stimuli in the activation of the eyes. For the time being we can only say that the evidence indicates, and we believe it to be so, that the development of allergy to uveal pigment is the essential predisposing factor necessary to permit the outbreak of sympathetic. ophthalmia, that some other unknown factor acts as the actual spark which initiates the process, and that once initiated, pigment allergy is again the factor which determines the characteristic histologic picture.

Discussion

DR CONRAD BERLIS, New York City-Those of you who have read the prinstaking researches of Doctor Woods must have been impressed as I was, by the enormous amount of work he has done, by his faithfulness in searching for the truth, and above all by his conservative conclusions My in terest has been principally in endeavoring to determine the importance of the skin

tests to uveil pigment
Intradermal Tests in General When skin tests are positive, they are almost positive proof of an allergic state, although this does not always determine the particular antigen to which the patient may be sensitized For example, it has been shown by Van Lecuwen that practically all allergic persons give positive reactions to certain antigens, while practically all nonallergic subjects give negative reactions to the same antigents A substance of this character is human dan druff I should like to know what studies Doctor Woods has made of the relation of his positive and negative skin test cases to other forms of allergy in these individuals, especially those with allergic history, family and personal, and sensitization to other sub-

Intradermal Tests to Urcal Pigment

Woods and Friedenwald have recently shown that there is a histologic difference in the skin reactions of persons who are allergic and those who are not allergic to intradermal injection of inveal pigment. If this is a specific reaction it is certainly an extremely important point in diagnosis Triedenwald (Notes on Allergy Theory of Sympathetic Ophthalmia, Ir Assoc Res Ophth, Fourth scientific meeting, Milwaukee, Wis, 1934, p 47) found these specific differences in five active cases of sympathetic ophthalmitis but they were all sent in two cases of "old healed sympathetic ophthalmitis" In view of the facts added by Doctor Woods, the examination of the skin after fourteen days seems to be an important part of skin testing and I wonder whether he could give us details of technic not given in his paper, i e, method of excision, fixation, etc Because of the common occurrence of multiple sensitization it is not surprising that the present tendency is to discount the value of skin tests in determin ing the specific antigen supposedly the cause of symptoms in many diseases

It might be profitable to study the reac tions to uveal pigment in seventy-three cases (see accompanying table) Of the seventy-three cases, twenty-five control tests were positive at one-half hour but only four of these were positive at twenty-four hours. One of the twenty-five patients was positive to the uveal pigment test at twenty-four hours and four were positive at one-half hour. In one true case of sympathetic ophthalmitis, confirmed microscopically, the uveal pigment tests was negative. The history of this case follows:

A. U., male, aged 23. Diagnosis: O. S.—acute postoperative uveitis, secondary glaucoma. O. D.—sympathetic ophthalmitis. The uveal pigment test and control were negative. The left eye was enucleated. The pathologic diagnosis was sympathetic ophthalmitis. Cultures from the eyeball both aerobically and anaerobically were negative after incubating the entire eyeball for five days (E. B. Burchell).

In four cases the uveal pigment test was positive. The diagnoses were: (1) detached retina probably secondary to chorioretinitis; (2) iridocyclitis, cause undetermined, although there was a 4+ reaction to intradermal tuberculin and the skin tests were markedly positive to autogenous vaccines of throat and gastrointestinal origin; (3) postoperative (cataract) iridocyclitis, O. D., and secondary sympathetic irritation, O. S., uveal pigment injections apparently not effective, also autogenous vaccines and lens antigen although the patient was sensitive to all these substances and to all cycloplegics. There was strikingly rapid subsidence of inflammation after evacuation of pus found in the right ethmoid region. Hypersensitivity to drugs also disappeared. (4) cataracts, O. U.; patient was also positive to lens antigen.

Two of the four patients who were undoubtedly hypersensitive to uveal pigment also showed marked reaction to skin tests with separate selected strains of autogenous vaccines. The patient with sympathetic ophthalmitis also had sinus disease (Dr. Craig) and was hypersensitive to autogenous vaccines from his nasopharynx. Rinaldi (Ann. di Ottal., 61:268, 1933), who studied the skin tests in 130 patients, found the intradermal tests negative in two true cases of sympathetic ophthalmitis in his series and that patients with normal eyes also showed some hypersensitiveness to uveal pigment. He concluded that uveal pigment tests have no clinical value.

These findings have led me to question whether allergy to certain bacterial toxins is not an important factor in the development of hypersensitivity to uveal pigment and whether it may not be an important factor in sympathetic ophthalmitis. The rôle of infection in allergy to pollens is fairly well established and Burky's uncompleted experiments with potent staphylococcus toxin are most important and should certainly be carried further.

I have made no studies of eosinophilia in the blood or tissues of these patients and although eosinophilia is not a constant phenomenon in allergy (Kahn and Stout) and may, for example, disappear from the nasal membranes in violent attacks of allergic rhinitis and in intercurrent bacterial infections, the majority of allergic patients have eosinophilia. I would like to know whether Doctor Woods has studied this phase of the problem.

TABLE—RESULTS OF UVEAL PIGMENT TESTS*

	Positive	Negative	Doubtful
Uveitis due to constitutional causes	3	14	5
Contusions with traumatic uveitis No sympathetic ophthalmitis		3	1
Endophthalmitis phacoanaphylactica (One eye lost after lens extraction)			1
Penetrating wounds involving uveal tract			-
Recovery without enucleation; no sympathetic ophthalmitis Enucleation of injured eye; no sympathetic ophthalmitis		16 3	1 1
Sympathetic ophthalmitis Foreign body (not verified pathologically) Penetrating wounds (not verified pathologically) Postoperative case (enucleation, cultures negative, pathologic		1 1	
report sympathetic ophthalmitis)		1	1
Optic atrophy Cataract Normal eyes	1	1 14 2	3
Total of all cases subdivided		56 73	13

^{*} Parke-Davis pigment used in 33 cases; Burky pigment in 40 cases.

In regard to treatment with uveal pigment-even though in the one case in which I used it faithfully it was apparently valueless-it seems to be scientific therapy in patients who are hypersensitive to uveal pigment as shown by skin tests even though its action may be mainly nonspecific. It is probable that tuberculin injections in symophthalmitis (Purtscher, Zischr. f. Augenh., 83:163, 1934; Meller, J.: Zischr. f. Augenh., 83:145, 1934) are nonspecific in their action and the Lowenstein technic is open to serious question according to the findings of the British Research Council (Wilson, G. S.: Medical Research, Council, London, Special Report Series, No. 182, 1933).

Rinaldi and Quaglio (Ann. di Ottal., 61: 295, 1933) also studied the intradermal tests in 140 patients with aqueous extract of bovine choroid devoid of pigment. In affections of the uveal tract 7.85 per cent were positive and four per cent of persons with normal eyes or in cases in which the uvea was not involved were positive; in two cases of sympathetic ophthalmitis and two of sympathetic irritation intradermal tests were negative. I would be greatly interested in knowing whether Doctor Woods has used uveal tissue devoid of pigment as an allergen. If he has, how do the histologic reactions differ in the cases in which pigment free uveal tissue is employed?

In conclusion, the more I see of intradermal tests in general the more conservative I become in attributing too much importance to them. However, when intra-dermal tests with fresh uyeal pigment are performed and are definitely positive at the end of twenty-four hours, they probably indicate sensitization to uveal pigment,

especially when control tests are negative. That they indicate that the person may or may not be developing sympathetic ophthalmitis has been, in my judgment, an unsettled question but Doctor Woods has presented the most convincing proof that I have seen. From studies of the literature and from our own experiments I am inclined to believe that hypersensitiveness to uveal pigment plays some part in the development of sympathetic ophthalmitis. Whether this is a primary or secondary part I do not know. My impression is that a more important factor is the sensitization of the patient to toxins from his own bacteria and that this is more likely to be the exciting factor which produces the more serious part of the disease. The organspecific hypersensitiveness to uveal pigment which is set up may be a factor in preparing the fellow eye for the elective effect of the toxins from other foci of infection. In the few cases I have seen which were supposed to have sympathetic ophthalmitis, there has always been the association of definite disease in the nasal accessory sinuses, and apparently the best results that I have seen from any treatment, occurred when the sinuses could be properly cared for.

In closing, I must express my appreciation of the enormous amount of scientific work Doctor Woods has devoted to this important subject and especially for the fact that his scientific mind has never permitted him to draw conclusions too hastily. Doctor Woods has said that the final evidence must be from experiments on human beings and in immunity it is most necessary to use human beings because the immunologic reactions seem to differ widely in man

and animals.

A SURVEY OF CASES OF SYMPATHETIC OPHTHALMIA OCCURRING IN NEW YORK STATE

HAROLD H. JOY, M.D., Syracuse

Reprinted, with additions by permission from the Archives of Ophthalmology November 1935, Vol. 14, pp. 733-741

The relative infrequency of sympathetic ophthalmia demands that every case be reported so that all may profit from the experience of others. With this thought in mind a questionnaire was sent to the 471 practicing ophthalmologists in New York state with the hope that an analysis might lead to some interesting observations. Of 212 (45 per cent) who replied 112 reported that they had never treated sympathetic ophthalmia, while eighteen stated that they had observed cases but that their records were either lost or not accessible. Eighty-two physicians reported 158 cases of sympathetic disease, in five of which the condition was apparently sympathetic irritation, and in two uveitis due to some other cause. There were 151 cases in which the clinical diagnosis seemed reasonably certain. Fifteen physicians reported from three to eight cases each; nineteen reported two each, and the remainder one each. Only forty-eight of the 126 enucleated exciting eyes were examined microscopically; in five the condition proved doubtful, and in two, not present, leaving forty-one in which the diagnosis was confirmed by microscopic examination.

Table I shows that thirty-four (92 per cent) occurred within the ten year period from 1925 to 1935. This compares with sixty-five per cent of the unconfirmed cases. Even if one assumes that the more recent cases are bound to predominate in returns from a questionnaire, these figures tend to show that sympathetic ophthalmia is not decreasing in frequency. Twentynine males and nine females were affected. In three cases the sex was not stated. The age incidence (Table II) ranged from three and one-half to seventy-seven years. Nine patients (22 per cent) were twelve years of age or younger. The periods of least incidence were those from thirteen to twenty and from thirty-one to fifty vears.

The exciting causes are shown in Table

No report	5	••••

sympathetic ophthalmia followed a perforating wound usually involving the uveal tract. In eight patients (19.5 per cent) it resulted from an intraocular operation; in five of these (12.2 per cent) the operation was a cataract extraction. In four patients (9.8 per cent) the sympathetic involvement followed a nonperforating injury. In the remaining three patients the condition was attributed, respectively, to a perforating corneal ulcer (2.5 per cent), phthisis bulbi following measles (2.5 per cent) and a necrotic sarcoma of the choroid (2.5 per cent).

The interval between injury and the onset of sympathetic inflammation (Table IV) ranged from nine days to forty-eight years. In only one patient was it less than three weeks. In sixteen patients the period was from three weeks to two months and in twelve from three months to one year. It is quite unusual that seven cases (Table V) were reported in which the interval was from five to forty-eight years. However, in two of these there is a question of the true interval. In one patient a fragment of steel had been in the lens for six years, producing a low grade uveitis with secondary glaucoma. The steel was removed with the lens in capsule, and this operation was followed seven weeks later by sympathetic inflammation in the fellow eye. Another patient had recurrent plastic iridocyclitis and secondary glaucoma forty-eight years after a perforating injury. Sympathetic ophthalmia followed nine days after enucleation with a gold ball implant, which may have been a factor in producing the disease. A case of perforating corneal ulcer is interesting in that the exciting eye had been quiet seventeen years when iridocylitis developed, and the other eye became involved. In a patient with phthisis bulbi following measles sympathetic inflammation occurred eleven years later. A patient whose eye was gored by the horn of a bull began to have accommodative and visual symptoms twenty-four years afterward, while another who received a gunshot injury appeared twenty years later with beginning involvement of the fellow eye.

The course was severe in twenty-five cases (62.5 per cent), moderate in six (15 per cent) and mild in nine (22.5 per

cent) The duration (Table VI) ranged from two weeks to two years. In eleven patients the discase ran a course of less than three months, in two it was unusually short—two and three weeks, respectively. In nine patients the duration was from three to six months, and in seven, from six months to two years. In three patients the disease had run its course when first observed, and in one it was still active at the time of the report.

The final vision is shown in Table VII Of fifteen patients with useful sight all except two had vision of 20/40 or better In 594 per cent the vision was 3/200 or less Comparison with seventy-four cases in which the diagnosis was not confirmed by microscopic examination suggests that there were instances of microrrect diagnosis

in the latter group

The multiplicity of therapeutic agents used makes an analysis of treatment difficult and of little value as there is no defimte relationship between any particular course of treatment and the ultimate outcome Treatment in sixty one per cent of 151 cases included large doses of salicylates (46 per cent) or of acetylsalicylic acid (15 per cent) in combination with injections of foreign proteins Mercury munctions, potassium iodide and pilocarpine hydrochloride (to produce sweats), either alone or in combination, was used in seventy-five per cent of the cases Intravenous therapy was used in twelve instances---: e, arsenicals in seven salicylates in two, typhoid vaccine in two and dextrose in one Other therapeutic agents reported used were diphtheria antiautohemotherapy, hyperpyrexia. erysipelas and prodigiosus toxins (Coley)

vaccine, tuberculin, thyroid extract, transfusions, todo cthylthioninamine, the mercury vapor are in quartz, tetanus antitoxin, useal pigment and cod liver oil Local treatment uniformly consisted mainly of mydriatics and hot or cold applications. Many of the reports showed careful chimination of foci or infection as well as examination by means of Wassermann and tuberculin tests.

The prophylactic value of enucleation is greatest immediately after the injury, and it diminishes markedly with lapse of time Dor' maintains that if enucleation is delayed as long as two weeks its effect is invariably lost, and the present series seems to confirm his contention (Table VIII) Six exciting eyes (146 per cent) were removed before any signs of sympathetic inflammation were noted in the fellow eyes. In only one instance was the period between injury and enucleation as short as two weeks, and in this one the disease ran a short mild course ending with vision of 20/15 In the other five cases in which the interval was twenty-six days or longer the condition was moderate or severe and of long duration and resulted in blind-The interval between enucleation and involvement of the fellow eve ranged from two days to two months, and in only two of the six cases was it less than two weeks Woods and Little 2 concluded from their series that sympathetic inflamination may be feared for at least two weeks after removal of the exciting eye. The statistics presented in this paper indicate that the period may be as long as two months

It is generally agreed that enucleation has little or no effect after sympathetic ophthalmia is established, and there are

not enucleated is due to retention of vision in the exciting eye in five instances. If one considers only the sympathizing eye one finds better visual results in the cases in which the exciting eye was enucleated. The figures indicate that removal of the exciting eye favorably influences the ultimate result in the sympathizing eye.

Nonperforating trauma as a cause of sympathetic ophthalmia is usually viewed with suspicion, and the percentage of cases caused by it in this series is unusually high (9.8 per cent). Of the four cases reported (Table X) two resulted from airgun injuries in children. The chief characteristic in each was hyphemia. The conjunctiva and cornea were intact, and there was no rupture of the sclera. In one case the hyphemia persisted for ten months, while in the other a low grade uveitis with hypotony developed. After periods of one year and of five months. respectively, the fellow eye became involved. In the third case there was a subconjunctival scleral rupture 10 mm, in length with no demonstrable break in the conjunctiva. The anterior chamber was

filled with blood, and vision was reduced to perception of light. The hyphemia persisted, and the globe became soft. Five weeks after the injury a mild attack of sympathetic inflammation occurred. The exciting cause in the fourth case may be open to question. The patient was struck by a baseball resulting in iridodialysis and intra-ocular hemorrhage but no rupture. The iridodialysis was repaired by the Key method five weeks after the injury. This was followed by a low grade indocyclitis with keratitis punctata. Three months after the injury and seven weeks after the operation the fellow eve became affected with sympathetic disease. While the first three cases demonstrate the appearance of sympathetic ophthalmia as the result of nonperforating trauma, the last is less convincing, as the operation may have been the exciting cause or at least a contributing factor. In all four cases hyphemia was a prominent feature.

The menace of sympathetic ophthalmia is ever present after intraocular surgical operations, particularly cataract extractions. Five of the eight postoperative cases in this series were attributed to cataract extractions (Table XI). One patient had

a hypermature cataract, one had chronic simple glaucoma and complicated cataract, and another was highly myopic. The interval between operation and involvement of the fellow eye varied from one to six months and the duration from three months to two years. Two cases were severe and three moderate. Four of the five cases resulted in loss of the perception of light, and in the fifth vision was reduced to perception of hand motion. The results in these few cases indicate that sympathetic oplithalmia due to cataract extraction is unusually violent, as maintained by Hambresin and others. Table XII compares the final vision in these cases with that in seventeen cases resultmg from cataract extractions in which the exciting eye was not examined microscopically, again suggesting that there were instances of incorrect diagnosis in the latter group.

In seven of the seventeen unconfirmed cases the exerting eye was not removed, and in all but two of these vision in the sympathizing eye was completely lost, one patient retaining vision of 20/30 and the other ability to see fingers at three feet (76 cm). Of four patients retaining

	Condition firmed Micros Examin	by copic	Condition Not Studied Microscopically	
Final Vision No perception of light Fingers at 3 feet or less 20/100-20/30	Cases 4 1 0 5	Per Cent 80 20 0	Cases 10 2 5	Per Cent 58.8 11.8 29.4

vision in the exciting eye one had vision of 20/100, one of hand motion and two of light.

Sympathetic diseases in children is usually severe and the outcome unfavorable (Table XIII). Nine patients (22 per cent) in this series were twelve years of age or younger. In five the course was severe; in one moderate; in two, mild, and in one it was not reported. Only two patients retained useful vision-20/40 and 20/20, respectively. This shows a marked contrast to twenty-one unconfirmed cases in children fifteen years of age or younger, once more suggesting mistaken diagnosis.

Summary and Conclusions

Sympathetic ophthalmia occurs less frequently than its diagnosis, since uveitis due to other causes, especially that due to tuberculosis, may give a similar clinical picture. A routine microscopic examination of the enucleated exciting eve is indicated if only for its statistical value. In this series of 151 cases in which the clinical features of sympathetic ophthalmia were present 126 exciting eyes were enucleated; forty-eight were examined microscopically, and in all but seven the diagnosis was confirmed. The forty-one cases in which the diagnosis was established showed a higher percentage of final visual defects than did the cases in which no microscopic examination was made. This raises the question of correct diagnosis which pathologic examination would have eliminated.

Analysis of the forty-one confirmed cases indicates that:

1. The frequency of sympathetic ophthalmia is not decreasing.

TABLE XIII.—COMPARISON OF FINAL VISION IN CONFIRMED AND NONCONFIRMED CASES IN CHILDREN

	Condition Confirmed by Microscopic Examination		Condition Not Studied Microscopically		
Final Vision No perception of light 3/200 or less	Cases 4 3 2	Per Cent 44.4 33.3 22.2	Cases 4 4 13 21	Per Cent 19 19 62	

- 2. Nonperforating trauma may not be a rare exciting cause.
- 3. Sympathetic ophthalmia due to cataract extraction is unusually violent and the prognosis grave.
- 4. The interval between injury to the exciting eve and the onset of sympathetic inflammation may vary from nine days to twenty-four years, or possibly to forty-eight
- 5. Sympathetic ophthalmia may be feared for at least two months after enucleation of the exciting eve.
- 6. Removal of the exciting eye before the onset of sympathetic inflammation does not favorably influence the ultimate outcome if the enucleation is delayed twenty-six days or more after the injury.
- 7. Sympathetic ophthalmia in children is unusually severe and the outcome unfavor-

Comparison of 126 cases (forty-one of which were confirmed) in which the exciting eve was removed with twenty-three cases in which there was no enucleation indicates that removal of the exciting eye favorably influences the ultimate outcome in the sympathetic eye.

In conclusion, I wish to thank the ophthalmologists who contributed to this report for their cooperation in answering the questionnaires.

FACE PAIN

Grorgi H Hyslop, M D, New York City

The subject which I am presenting is one which I believe may be of interest because it is not only a topic which frequently presents itself to the clinician, but involves problems of anatomy and physiology which are not yet settled. Being reminded of our lack of knowledge should not only stimulate inquiry, but also enable us to avoid the pitfalls of improper therapy based upon misconceptions or ignorance.

Face pun may be the result of abnormality in tissues supplied by the trigeminal nerve and its connections. It may also be caused by abnormality directly affecting, in a structural way, the peripheral and central portions of the trigeminal nerve and its connections Disease of either character frequently complicates the clinical problem by causing discomfort or pain in areas not normally supplied by the trigenimal nerve Some patients will complain of discomforts in the occiput, neck, and even the shoulder Certain varieties of headrche may be clinically related to face pain. I will try to restrict myself to pain in the face

Touch and discriminative sense stimuli of the face and front part of the head are carried in the trigeminal nerve. Pain and temperature stımulı arc transmitted through the trigeminal nerve Embryologically, the first or ophthalmic division of this nerve is separate and distinct from the other two divisions, and the oculo motor nerve can be regarded as its motor component Pressure or deep pain of the face, and perhaps vibratory sensibility stimuli, are transmitted by the facial nerve

The peripheral portion of the trigeninal nerve enters the pons Touch and discrimination sense pass from the pons to the thalamus by way of a small tract lying medial and dorsal to the median lemniscus Pain, temperature, and some tactile fibers form what is called the descending root of the trigeninal nerve which ends in a nucleus extending into the upper cervical portion of the spinal cord. Then, after

decussiting, ascending central fibers pass to the thilamus by way of the spinothalium tract

Deep pain sensibility, which is carried by the facial nerve, is transmitted by the geniculate ganglion of this nerve, via the nervous intermedius, to the poins

The connections of the trigement nerve with the vegetative nervous system have

not been finally established

The accompanying table is convenient for enumerating the conditions in which face pain may occur. It should be remembered that face pain, as a symptom, may occur in the absence of structural pathology directly affecting and involving the central or peripheral pathways of the trigenimal nerve.

The seeming predilection for involvement of the ophthalium division in cases of post-infectional neuralgia, suggests that the avenue of entrance of such infections (particularly influenza) to the body is the upper nasopharyna. The same may hold true in the instances of herpes affecting the ophthalmic division

In glaucoma, the supraorbital and frontal pain is regarded as due to pressure on the selera and irritation or pressure

affecting the ciliary nerves

The special variety of face pain called "atypical facial neuralgia" occurs prob ably just as frequently as true trigeminal neuralgia. It is always a difficult clinical problem, and I think deserves detailed comment The pain itself has certain com mon characteristics in the majority of It tends to be constant, with cases exacerbations influenced by barometric conditions, fatigue, and emotional tension It may be associated with migramous headaches, and vasomotor phenomena may be prominent. The discomfort or prin itself is usually described as deep within, and there is no superficial hyper esthesia or any trigger zone Patients are apt to be vague in describing their dis comfort, and use many terms-boring, grinding, and aching are words often used The discomfort often radiates to the back of the head, neck, and shoulder

Occasionally the pain distribution may be restricted to one or more branches of the trigeminal nerve.

Sluder directed attention to the possibility that such pain is due to a disorder of the vegetative nervous system.

No true afferent or sensory fibers have been found in the vegetative nervous system. Sensation from the viscera and blood vessels is carried by fibers which travel in the vegetative nervous system through the sympathetic trunks, and then to the posterior root ganglia by way of the white rami. Davis and Pollock¹ account for pain in the head and face in certain cases, in which the vegetative nervous system or sympathetic fibers are a factor, in the following way:

Some stimulus produces a reflex in the vegetative nervous system; its efferent fibers transmit impulses which bring about a mechanical or chemical change in tissues; the special visceral afferent fibers in these tissues then transmit sensation via the portion of the trigeminal nerve supplying the tissues affected.

However, various writers have proposed that different portions of the vegetative nervous system may be involved and responsible for reflex pain in the face.

Woollard² described the occurrence of degeneration in the mesencephalic root of

the fifth nerve after resection of the third nerve. This suggests that the fifth nerve may carry sensory fibers originating in other nerves. Confirmation of his findings would aid in explaining some instances of atypical facial pain.

Blier³ refers to visceral afferent fibers from the nose being carried in the greater superficial petrosal nerve. Stewart and Lambert⁴ deny the occurrence of visceral afferent fibers in the sphenopalatine ganglion and nasopalatine nerves.

The Sluder syndrome, in which the pain is prominent in the area supplied by the maxillary or second branch of the trigeminal nerve, seems to be caused by infection in the paranasal sinuses, and particularly in the tissues of the upper nasal cavity.

Frazier⁵ reported that electrical stimulation of the superior cervical sympathetic ganglion may produce pain in the trigeminal distribution zone. Peet⁶ discussed the possible role of the sympathetic nervous system in atypical facial neuralgia.

As far as is known, no sensory fibers have been identified entering the superior cervical sympathetic ganglion. But from this ganglion, fibers pass through the glossopharyngeal, vagus, and upper cervical nerves. Peet called attention to a

group of fibers passing between the nodosum ganglion of the vagus and the superior cervical sympathetic ganglion. Whether these fibers originate in the sympathetic or the vagus is not known. Peet recorded one case in which stimulation of these fibers increased pain in the cheek and cutting the fibers stopped the atypical neuralgia pain.

He also notes that electrical stimulation of the great superficial petrosal nerve will produce pain but not the pain of "atypical neuralgia." It is possible that since deep pressure pain is characteristic of "atypical neuralgia," transmission may be through the facial nerve. There is no clinical or anatomical evidence as yet in favor of

this hypothesis.

Fay notes that the pain of an atypical facial neuralgia disappeared when a spinal anesthesia reached the level of the first thoracic segment. This and other observations led Fay to suggest that relief of such pain by removal of the upper thoracic sympathetic chain and stellate ganglion is due to interrupting pain fibers which accompany the blood vessels to the face and which enter the cord in the upper thoracic segments. He also suggests that branches of the vagus nerve associated with the cranial vessels may transmit pain.

Mixter and White⁸ report a case in which the pain was relieved by injection or removal of the cervicodorsal and second dorsal ganglia. This procedure extends the anatomical possibilities not only for pathways of pain in the face, but

for relief of this symptom.

I have seen a number of patients at Memorial Hospital who have malignant disease affecting the lymph nodes in the neck, and who complain of pain in the trigeminal area distribution, as well as in the upper cervical segmental areas. I have been unable to find any evidence of intracranial extension of malignancy in these cases, some of whom have remained under observation for a period of months. Such pain may develop as a reaction to a recent course of irradiation treatment. It is common to observe that induration and fibrosis in the neck, especially over the carotid bulb, caused by extensive irradiation therapy, precede the appearance such pain. Assuming that the malignant disease has not invaded the base of the skull, it seems possible that the face pain is a reflex response to irritation of the sympathetic fibers running along the blood vessels to the skull and brain. Relief of such pain is a difficult problem, since frequently the extent and degree of induration are such that one cannot attempt any operation through the tissues affected.

Pottenger^o states that he has seen patients with facial pain which he regarded as a distant reflex from chest or lung disease, and suggests that the vagus nerve carries the afferent impulses which are transmitted centrally by connections with the descending root of the trigeminal

nerve.

Some writers stress the belief that patients with atypical facial neuralgia are psychoneurotic, and that treatment, to be effective, must center upon psychotherapy. A generation ago the medical text books still included statements of similar character about some patients with tic douloureux. With the perfection of surgical treatment of this condition, psychotherapy has been omitted as a means of treatment. and such patients are no longer regarded as having their pain as a psychoneurotic symptom. One cannot doubt that a psychoneurotic individual who is suffering from a painful condition may materially complicate the problem of diagnosis and treatment. The words of Sir James Paget10 are perhaps applicable to such situations.

For pain expected, watched for, long thought of, will come: will come in or from the nerve center and be as bitter as any from the nerve's ends... and, conversely, the longer and more often the attention can be diverted from any pain, the less does the power of discerning the pain become, just as the muscular or any other sense when out of practice loses some of its cunning.

I do not doubt that some sufferers from atypical neuralgia are psychoneurotic. However, somatic painful disease can readily bring to the surface latent psychic conflicts. The relief of this particular type of pain by such procedures as Sluder, Peet, and Fay have described, and the uncertainty and incompleteness of our anatomical knowledge should lead to an open mind on our part.

Case 1. Fig. 1 shows one of a series of skull films which enabled us to make a

diagnosis in a forty-eight year old woman who entered the hospital because of what seemed to be tic douloureux involving the first and second divisions of the right trigeminal nerve. She had had her paroxysms for eighteen years, and had been given a dozen or more alcohol injections.

Neurological examination showed a very slightly diminished sensibility in the area supplied by the ophthalmic division of the right trigeminal nerve. This sign was regarded as the result of the many alcohol injections. The patient's physical status was otherwise normal.

This illustration shows an osteoma at the base of the skull which was found to lie in close proximity to the foramina of exit of the first and second branches of the right trigeminal nerve. The tumor was removed by operation. (Neurological Institute.)

Case 2. Fig. 2 reveals abnormalities discovered in a film of the base of the skull taken so as to show the middle fossa. The patient was a twenty-eight year old woman who for six months had complained of pain in the right ear, lower border of the right jaw, and the right temple. This pain had been intermittent, and there were paroxysms which were similar to those observed in tic douloureux. She also was troubled with vertigo and tinnitus in the right ear.

Examination showed sensory impairment in the area supplied in the second and third divisions of the right trigeminal nerve, questionable weakness of the muscles supplied by the right facial nerve, and a right sided nerve deafness and slightly abnormal tendon reflexes on the left side.

This patient was difficult to examine, because of her unstable personality, and the objective findings, except for the nerve deafness, varied so much that an organic diagnosis was not easy. Because of the nerve deafness, we felt satisfied that the pain had an organic basis.

Routine stereoscopic x-ray films of the skull did not show any abnormality. A careful examination of the upper pharynx showed what seemed to be a tumor mass and a biopsy examination of tissue from the pharynx showed that the patient had a Schwenke tumor. We then took a film of the base of the skull. As can be seen, the tumor had invaded the floor of the middle fossa on the right side, and was producing symptoms by involvement of the cranial nerves. As time passed, facial weakness and external rectus palsy appeared on the right side. (Neurological Institute.)

I have perhaps given more attention than necessary to the subject of atypical neuralgia. I wish that our knowledge as to the cause and method of relief of this type of face pain were more complete. It seems evident, however, that face pain

Fig. 1. Osteoma at base of skull, posterior to Sella Turcica. (Case 1.) (Neurological Institute)

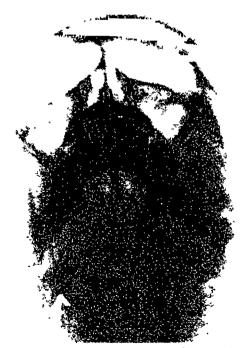

Fig. 2. Film of base of skull showing invasion and destructive changes in right middle and posterior fossae. (Case 2.) (Neurological Institute)

may be due to disturbance of the sympathetic function, and that the well-known diffuseness and complexity of sympathetic conduction make it necessary to investigate relatively distant regions for the source of such pain,

Treatment of face pain obviously depends upon measures which will influence the cause of this symptom. Symptomatic measures include using the common analgesic drugs, massage, and other forms of physiotherapy, and in the case of patients with true trigeminal neuralgia or tic douloureux preceding decision as to operation, inhalation of trichlorethylene, gelsemium, diathermy, and application of low or medium voltage x-ray may be tried. 129 EAST 69TH ST.

CASE REPORT

TRAUMATIC DIVISION OF TRANSVERSE COLON AND COMPLETE LOSS OF GREATER OMENTUM, WITH RECOVERY

VINCENT D. LEONE, M.D., Niagara Falls

The following case is reported because it shows the extent to which the gastrointestinal tract and peritoneum can be traumatized, with contamination incident to such severe trauma, and still recover.

- In an exhaustive review of literature since 1920, I can find no report of a case of traumatic loss of the entire omentum. Complete traumatic division of the transverse colon with recovery is also apparently rare. Savage¹ states that wounds of the large intestine are twice as fatal as those of the small intestines. G. Gordon-Taylor2 states by reason of the size of this portion (large intestine) of the intestinal tract, its wounds are mostly of perforations or tears and the bowel is rarely completely divided, Regarding treatment, Gordon-Taylor states whole experience of the surgery of the war demonstrated that suture suffices in an overwhelming majority of cases of injury to the colon.

In the case which is the subject of this report the transverse colon was completely divided and the entire omentum had been torn from its attachment to the transverse colon.

M.N., white, male, age 26, taxi driver, was admitted to the Niagara Falls Memorial Hospital on May 31, 1935, at 8:35 A.M. with a history that the man had attempted suicide by slashing his abdomen, wrists and legs with a razor. Dr. E. A. Cortese, the attending physician, who assisted me with the operation, stated that after the evisceration of the bowel, in his presence, the patient suddenly grasped the protruding omentum and literally tore it off from its attachment.

It was later revealed that this man had been under antiluctic treatment for the past four years. For a period of a few weeks he had been acting queerly, was depressed and introspective. The morning of his admission he had attacked his wife with a razor.

On admission the patient had been administered one half grain of morphine sulphate, and about one hour later, at the time of my examination, he had reacted fairly well from the initial shock. He was lying quietly on the table, pulse was 120, respirations, 24. Examination of the abdomen

with several large ecchymotic areas. The mucous membranes of the mouth and the pharynx showed numerous petechiae. The cervical lymph glands were enlarged. There were rales and dullness over the left upper chest. The spleen was not palpable. Roentgenograms of the chest showed bilateral pulmonary tuberculosis with cavitation.

The hemoglobin was seven grams, red blood cells 3,100,000, white blood cells 8,500. The differential count was normal but there was complete absence of platelets in the smear. The bleeding time was markedly prolonged. The clotting time was six minutes and clot retraction was poor. The urine was negative except for a few red blood cells. The blood Wassermann reaction was negative.

On June 22, a transfusion of 500 cubic centimeters of citiated blood was given. The pulse and temperature remained elevated. On the evening of June 23rd, she complained of severe, sharp pain in the face; the following morning she was found

dead in bed.

Necropsy findings: On removal of the brain a large hemorrhage was found in the upper and outer aspect of the left lobe of the cerebellum, beneath the leptomeninges. On section, the hemorrhage extended into the cerebellar structure a distance of three centimeters. The brain stem was displaced to the right. There was no evidence of hemorrhage into the cerebrum or ventricles. Extensive pulmonary and glandular tuberculosis was present. Other organs showed many small hemorrhages.

Fig. 1. Large intracranial hemorrhage with rupture of the cortex. Case III.

Case III. S.M., a forty-eight year old housewife, was admitted to the Rochester Municipal Hospital, April 28, 1929. She complained of jerky movements and of weakness of the muscles of the left side of the body. These symptoms began suddenly the morning of admission. One hour later she lost consciousness for five minutes. The past history was negative except that for six weeks prior to admission she had bruised easily and "black and blue spots" had appeared without known antecedent trauma.

The patient was mentally clear and not acutely ill. The skin and mucous membranes showed innumerable small and large hemorrhages. The examination of the heart, lungs, and abdomen was negative. Neurological examination revealed weakness and clonic movements of the left lower face, arm and leg. The tendon reflexes were increased on the left. A Babinski sign could not be elicited.

The hemoglobin was 9.75 grams, red blood cells 3,000,000, white blood cells 7,500. The differential count was normal. No platelets were seen in the smear. The bleeding time was prolonged. The clotting time was six minutes. The blood Wassermann reaction was negative. Lumbar puncture revealed bloody spinal fluid under normal pressure

Several hours after the lumbar puncture, which was done on the evening of admission to the hospital, she complained of severe headache and vomited. The following morning she became comatose. The right pupil was dilated and there was complete paralysis of the left arm and leg. Death occured three hours after the onset of coma.

Necropsy findings: On opening the dura an extensive hemorrhage was found over the right parietal lobe and a smaller one was seen over the anterior pole of the right temporal lobe. Section of the brain revealed a large fresh hemorrhage measuring six by six by six centimeters, located in the anterior superior part of the right parietal lobe. It had ruptured through the cortex (Fig. 1). A similar but smaller hemorrhage was found at the tip of the right temporal lobe.

Case IV. C.B., an eighteen year old student, was admitted to the Strong Memorial Hospital, February 14, 1934. He complained of weakness, and of bleeding from the gums. Six months before admission ecclymotic areas had appeared over the legs without known antecedent trauma. There had been several attacks of severe nose bleed and of bleeding from the gums over a period of several weeks prior to admission. The past history was negative except that he had not enjoyed his usual good health

may be due to disturbance of the sympathetic function, and that the well-known diffuseness and complexity of sympathetic conduction make it necessary to investigate relatively distant regions for the source of such pain.

Treatment of face pain obviously depends upon measures which will influence the cause of this symptom. Symptomatic measures include using the common analgesic drugs, massage, and other forms of physiotherapy, and in the case of patients with true trigeminal neuralgia or tic douloureux preceding decision as to operation, inhalation of trichlorethylene, gelsemium, diathermy, and application of low or medium voltage x-ray may be 129 EAST 69TH ST.

CASE REPORT

TRAUMATIC DIVISION OF TRANSVERSE COLON AND COMPLETE LOSS OF GREATER OMENTUM, WITH RECOVERY

VINCENT D. LEONE, M.D., Niagara Falls

The following case is reported because it shows the extent to which the gastrointestinal tract and peritoneum can be traumatized, with contamination incident to such severe trauma, and still recover.

In an exhaustive review of literature since 1920, I can find no report of a case of traumatic loss of the entire omentum. Complete traumatic division of the transverse colon with recovery is also apparently rare. Savage1 states that wounds of the large intestine are twice as fatal as those of the small intestines. G. Gordon-Taylor2 states by reason of the size of this portion (large intestine) of the intestinal tract, its wounds are mostly of perforations or tears and the bowel is rarely completely divided. Regarding treatment, Gordon-Taylor states whole experience of the surgery of the war demonstrated that suture suffices in an overwhelming majority of cases of injury to the colon.

In the case which is the subject of this report the transverse colon was completely divided and the entire omentum had been torn from its attachment to the transverse colon.

M.N., white, male, age 26, taxi driver, was admitted to the Niagara Falls Memorial Hospital on May 31, 1935, at 8:35 A,M. with a history that the man had attempted suicide by slashing his abdomen, wrists and legs with a razor. Dr. E. A. Cortese, the attending physician, who assisted me with the operation, stated that after the evisceration of the bowel, in his presence, the patient suddenly grasped the protruding omentum and literally tore it off from its attachment.

It was later revealed that this man had been under antiluetic treatment for the past four years. For a period of a few weeks he had been acting queerly, was depressed and introspective. The morning of his admission he had attacked his wife with a razor.

On admission the patient had been administered one half grain of morphine sulphate, and about one hour later, at the time of my examination, he had reacted fairly well from the initial shock. He was lying quietly on the table, pulse was 120, respirations, 24. Examination of

100

showed a few loops of the small bowel lying outside of the abdomen, as well as the transverse colon which was completely severed to the gastrocolic ligament. The omentum was missing except for a small strip attached to the transverse colon. There were also lacerations of both forearms and both legs below the knees. Patient was prepared immediately for operation. The skin was painted with tincture of merthiolate after the bowel was covered with warm sterile pads. Two intestinal clamps were placed to close the severed ends of the transverse colon, and then the exposed bowel was flushed with copious amounts of sterile saline. An end to end anastomosis of the transverse colon was made and the suture line was reinforced with a small strip of the remaining omentum. There was no injury of the small bowel lying outside of the abdomen, so the incision was enlarged, bowel replaced, and thorough examination made of the stomach and remaining bowel. A Penrose drain was placed at the site of the anastomosis and one at the ileocecal fossa. 200 c.c. of amfetin was left in the abdomen, a large portion of which drained through the drains within the next few hours. The abdomen was closed in layers and reinforced by silk worm sutures. 1000 c.c. of normal saline was given by hyperdermoclysis.

Convalescence was somewhat stormy. During the first week the temperature varied from 101.6 to 103.6; pulse 110 to 120, respirations, 26 to 40. Strange as it may seem his mental condition appeared perfectly normal during this time. He cooperated well and talked rationally. The first four days he was given 3000 c.c. of 5 per cent glucose in normal saline solution daily. Nothing was given by mouth until the third day when he was started on peptonized milk. On the third

day he had his first bowel movement which was liquid in character. 0.1 c.c. of B. coli mixed bacterial antigen was given intradermally every other day. Drains were shortened each day and the one placed next to the anastomosis removed on the fourth day, the other on the sixth day. There was considerable purulent drainage starting on the third day, and on the fifth to eighth day it was fecal in character. The sinus remaining after drains were removed was irrigated with Dakin's solution daily and within two weeks was entirely healed.

There was nothing unusual in the routine blood counts and urinalyses. Blood Wasserman was one plus in alcoholic and two plus in the cholesterinized antigen. Spinal fluid Wassermann was negative in both alcohol and cholesterinized antigens. The spinal fluid was not under pressure; there were eight cells per cmm, one plus globulin and Fehling's solution was reduced. The collodial gold curve fell in luetic zone. On July 3rd, patient was removed to the Buffalo State Hospital for malarial treatment for cerebral lues. At the time of his discharge his abdomen was completely healed, he was having daily bowel movements and complained of no gastric distress after eating. Personal communication with his attending physician at the Buffalo State Hospital on a recent date revealed that he was having no difficulty from his gastrointestinal tract.

MEETING OF THE AMERICAN COLLEGE OF PHYSICIANS

The Twentieth Annual Session of the American College of Physicians will be held in Detroit with headquarters at the Book-Cadillac Hotel, March 2-6, 1936.

Dr. James Alex. Miller, of New York City, is President of the College, and has arranged a program of general scientific sessions of great interest to those engaged in the practice of Internal Medicine and associated specialties. Dr. Charles G. Jennings, of Detroit, is the General Chairman of the Session, and is in charge of the program of clinics and demonstrations in the hospitals, medical schools and other Detroit institutions. Dr. James D. Bruce, Vice President in Charge of University Relations,

University of Michigan, is Vice Chairman of the Committee on Arrangements, and has in charge the preparation of an all-day program to be conducted at the University of Michigan on Wednesday, March 4. Dr. Walter B. Cannon, Professor of Physiology at Harvard University Medical School, will deliver the annual Convocation Oration on "The Role of Emotion in Disease." Dr. Miller's presidential address will be on "The Changing Order in Medicine." About fifty eminent authorities will present papers at the general scientific sessions, while clinics and demonstrations will be conducted at the Harper, Receiving, Ford, Grace, Herman Kiefer and Children's Hospitals, of Detroit.

PURPURA HEMORRHAGICA WITH INTRACRANIAL HEMORRHAGE

Paul H. Garvey, M.D., Rochester

DORAN J. STEPHENS, M.D., Rochester

From the Department of Medicine, University of Rochester School of Medicine and the Medical Clinic of the Strong Memorial and Rochester Municipal Hospitals, Rochester, N. Y.

It has long been recognized that sudden and often fatal intracranial hemorrhage may occur in patients with purpura hemorrhagica. A review of the recent literature indicates that the frequency of this complication is underestimated. In 1934, Geiger1 was able to collect only twentyfive instances of intracranial bleeding in purpura hemorrhagica. In his own series of thirty-six cases, two of five fatalities were due to cerebrospinal hemorrhage. Several observers 2.3.4 have recorded approximately the same incidence of intracranial hemorrhage as a cause of death in small series of cases.

In this clinic, since 1926, a diagnosis of purpura hemorrhagica has been made in thirty cases. Of these, ten ended fatally and the cause of death in seven was an intracranial hemorrhage. In five the diagnosis was confirmed at autopsy.

Report of Cases

Case I. E.B., a nineteen year old student. was admitted to the Strong Memorial Hospital, January 6, 1934. He complained of bloody urine and of bleeding into the skin and mucous membranes. He was considered well until two years previously, at which time a tooth had been extracted, with profuse bleeding from the socket over a period of ten days. Since then he had noticed that he bled freely from minor cuts, bruised readily and had occasional bloody and tarry stools. Three weeks prior to admission he had an acute respiratory infection, followed by many petechiae, frequent nose bleeds, bleeding from the gums, and hematuria.

The patient was a tall, pale youth who appeared chronically ill. The vital signs normal. There were numerous petechiae over the skin and mucous membranes. There were several large ecclymotic areas over the anterior surface of the legs. The fundi showed several old hemorrhages. The physical examination was otherwise

negative.

The hemoglobin was 11.4 grams per 100 cubic centimeters, red blood cells 3,300,000 per cubic millimeter, white blood cells 10,850 per cubic millimeter. The differential formula was normal. The smear showed only one platelet in every twenty-five oil immersion fields. The bleeding time was sixty minutes. The clotting time (Howell) was eight minutes. The clot did not retract. Repeated urine examinations showed both gross and microscopic blood. Stools were negative for occult blood. The blood Wassermann test was negative.

The patient was given three blood transfusious of 300 cubic centimeters each, without improvement. On the evening of January 15th, he complained of a severe right frontoparietal headache followed by weakness of the left side of the body. Death occurred three hours after the onset of the headache.

Necropsy findings: External examination of the brain revealed a small hemorrhage in the subarachnoid space along the ventral surface of the pons and medulla. On section, the right frontoparietal lobe showed a hemorrhage measuring three by four centimeters which had ruptured into the right lateral ventricle. Microscopic examination of the brain revealed numerous small hemorrhages in the pons, and others in the immediate neighborhood of the large intra-cerebral hemorrhage.

Case II. S.S., a twenty-two year old girl, was admitted to the Rochester Municipal Hospital, June 20, 1934. She complained of "black and blue spots" over her body and of bleeding from the nose and mouth. These symptoms began on the day of admission to the hospital. Five weeks before she had noted enlargement of the glands of both sides of the neck; these had gradually re-The glandular enlargement was accompanied by fever and malaise. The past history was irrelevant.

The patient was a well-nourished girl who appeared acutely ill. The temperature was 38.2° C. and the pulse was 128. There was a fine purpuric eruption over the body,

Read at the Annual Meeting of the Medical Society of the State of New York, Albany, May 15, 1935

with several large ecchymotic areas. The mucous membranes of the mouth and the pharynx showed numerous petechiae. The cervical lymph glands were enlarged. There were rales and dullness over the left upper chest. The spleen was not palpable. Roentgenograms of the chest showed bilateral pulmonary tuberculosis with cavitation.

The hemoglobin was seven grams, red blood cells 3,100,000, white blood cells 8,500. The differential count was normal but there was complete absence of platelets in the smear. The bleeding time was markedly prolonged. The clotting time was six minutes and clot retraction was poor. The urine was negative except for a few red blood cells. The blood Wassermann reaction was negative.

On June 22, a transfusion of 500 cubic centimeters of citrated blood was given. The pulse and temperature remained elevated. On the evening of June 23rd, she complained of severe, sharp pain in the face; the following morning she was found dead in bed.

Necropsy findings: On removal of the brain a large hemorrhage was found in the upper and outer aspect of the left lobe of the cerebellum, beneath the leptomeninges. On section, the hemorrhage extended into the cerebellar structure a distance of three centimeters. The brain stem was displaced to the right. There was no evidence of hemorrhage into the cerebrum or ventricles. Extensive pulmonary and glandular tuberculosis was present. Other organs showed many small hemorrhages.

Fig. 1. Large intracranial hemorrhage with rupture of the cortex. Case III.

Case III. S.M., a forty-eight year old housewife, was admitted to the Rochester Municipal Hospital, April 28, 1929. She complained of jerky movements and of weakness of the muscles of the left side of the body. These symptoms began suddenly the morning of admission. One hour later she lost consciousness for five minutes. The past history was negative except that for six weeks prior to admission she had bruised easily and "black and blue spots" had appeared without known antecedent trauma.

The patient was mentally clear and not acutely ill. The skin and mucous membranes showed innumerable small and large hemorrhages. The examination of the heart, lungs, and abdomen was negative. Neurological examination revealed weakness and clonic movements of the left lower face, arm and leg. The tendon reflexes were increased on the left. A Babinski sign could not be elicited.

The hemoglobin was 9.75 grams, red blood cells 3,000,000, white blood cells 7,500. The differential count was normal. No platelets were seen in the smear. The bleeding time was prolonged. The clotting time was six minutes. The blood Wassermann reaction was negative. Lumbar puncture revealed bloody spinal fluid under normal pressure.

Several hours after the lumbar puncture, which was done on the evening of admission to the hospital, she complained of severe headache and vomited. The following morning she became comatose. The right pupil was dilated and there was complete paralysis of the left arm and leg. Death occured three hours after the onset of coma.

Necropsy findings: On opening the dura an extensive hemorrhage was found over the right parietal lobe and a smaller one was seen over the anterior pole of the right temporal lobe. Section of the brain revealed a large fresh hemorrhage measuring six by six by six centimeters, located in the anterior superior part of the right parietal lobe. It had ruptured through the cortex (Fig. 1). A similar but smaller hemorrhage was found at the tip of the right temporal lobe.

Case IV. C.B., an eighteen year old student, was admitted to the Strong Memorial Hospital, February 14, 1934. He complained of weakness, and of bleeding from the gums. Six months before admission ecchymotic areas had appeared over the legs without known antecedent trauma. There had been several attacks of severe nose bleed and of bleeding from the gums over a period of several weeks prior to admission. The past history was negative except that he had not enjoyed his usual good health

following an attack of whooping cough three years before.

The patient was a thin, pale youth who appeared chronically ill. There were several petechiae over the face, neck, and extremities, and numerous small hemorrhages over the mucous membranes of the nose and gums. Ophthalmoscopic examination revealed numerous retinal hemorrhages. The physical examination was otherwise negative.

The hemoglobin was 5.5 grams, red blood cells 1,860,000, white blood cells 1,900. Differential count: neutrophiles, forty-two per cent; lymphocytes, fifty-four per cent; monocytes, four per cent. The red blood cells showed marked hypochromia. No platelets were seen in several smears. The bleeding time was thirty minutes. The clotting time was thirty minutes. Urine and stool examinations revealed the presence of blood. Blood cultures were repeatedly negative until one week before death when Bacillus coli was cultured.

Bleeding into the skin and from the mucous membranes continued in spite of frequent transfusions. On April 11th, he suddenly became comatose and died several hours later.

Necropsy findings: A large subarachnoid hemorrhage was found over the base of the brain covering the cerebellum and the brain stem (Fig. 2). On section of the brain numerous petechiae were found beneath the ependyma in all ventricles.

Case V. E.L., a 33 year old laborer, was admitted to the Rochester Municipal Hospital, April 2, 1934. Six days before admission to the hospital he had received an injection of sulpharsphenamine, which was followed by the appearance of red spots over his body. Three days later he noticed blood in his urine. On the morning of admission he awoke suddenly with a feeling of dizziness, followed by nausea and vomiting. The past history was negative except that a diagnosis of primary syphilis had been made five months before.

The patient appeared acutely ill. He avoided any movement of the head because it increased the dizziness. The skin was practically covered with petechiae measuring two to four millimeters in diameter. The physical examination was otherwise negative.

The hemoglobin was 11.4 grams, red blood cells 3,800,000, white blood cells 11,700. Differential count: neutrophiles, ninety-four per cent; lymphocytes, four per cent; monocytes, one per cent; cosinophiles, one per cent. No platelets were seen in the blood films. The urine was grossly bloody. Fourteen hours after admission he sud-

denly developed a severe headache shortly followed by cessation of respirations and death.

Necropsy findings: In the cerebellopontine angle there was a hemorrhage beneath the arachnoid measuring 1 x 1.5 centimeters in diameter, extending to the right of the midline. On section of the brain, a large hemorrhage was found in the right cerebellar lobe. It measured three and one-half centimeters at its greatest diameter. The third ventricle was filled with blood. The cerebrum showed no evidence of hemorrhage.

Discussion

In dealing with a syndrome in which widespread hemorrhage is the cardinal feature, it is not surprising that hemorrhage occurs in the brain and meninges with considerable frequency. Perhaps the most common type of bleeding into the central nervous system is in the occurrence of small, capillary ring hemorrhages which occur, as a rule, in both the white and gray matter of the cerebrum and cerebellum-the so-called brain purpura (Fig. 3). Gordon⁵ described a case in which profound changes in the nervous system, presumably due to small hemorrhages, were confined to the gray matter of the brain and spinal cord. The clinical symptoms produced by this type of bleeding are minimal and are usually obscured by the symptomatology of large hemorrhages located elsewhere,

It has been our experience, and that of

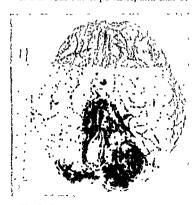

Fig. 2. Large localized subarachanoid hemorrhage. Case IV.

others,^{2,4} that the most common cause of death in purpura hemorrhagica is the development of one or more large intracranial hemorrhages. In discussing the signs and symptoms produced by these hemorrhages Longcope⁶ and Geiger¹ state

While cerebral hemorrhage is one of the feared complications of purpura hemorrhagica, it does not necessarily imply a fatal prognosis. Several instances of spontaneous recovery from subarachnoid bleeding have been recorded.

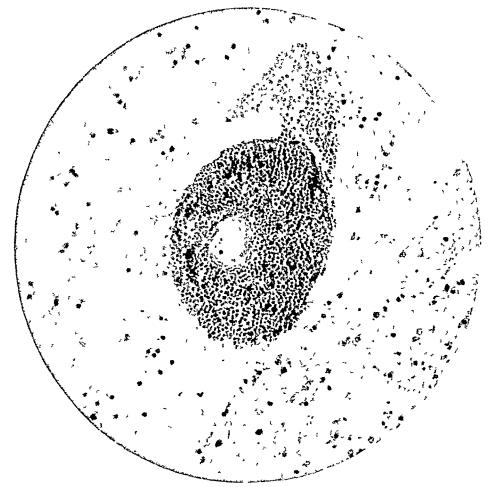

Fig. 3. Capillary ring hemorrhage. Case I.

that the cases can usually be divided into three groups. The first, and probably the largest group, is characterized by the sudden development of focal signs, usually those of a hemiplegia. A second group with meningeal bleeding presents the usual symptoms and signs of subarachnoid hemorrhage. The third group includes instances of coma and convulsions. A fourth group might be added to include those cases which present the syndrome of cerebellar apoplexy. It is of interest that the cause of death in two of our patients (Cases II and V) was a cerebellat hemorrhage.

One of our patients, a boy of twelve years, was admitted to the hospital about a year ago with a history of repeated and persistent nose bleeds of four months' duration. Headache, diplopia, drowsiness, vomiting, and convulsions had been present intermittently for the same length of time. On examination, hemorrhages were seen in the skin and mucous membranes. The blood findings were characteristic of idiopathic purpura hemorrhagica. The neurological examination revealed a sixth nerve palsy. The spinal fluid contained 300 red blood cells per cubic millimeter; the spinal fluid pressure was 240 milli-

meters of water. It was thought that he might have subdural bleeding but several burr holes revealed no evidence of this condition. The following day splenectomy was done. Platelets appeared in the peripheral blood a few hours after operation and the neurological signs promptly improved. Since splenectomy, one year ago, he has remained well, without return of hemorrhagic manifestations or neurological symptoms. This case illustrates the apparent value of splenectomy in the control of the bleeding.

The treatment of the intracranial complications of purpura hemorrhagica is not very satisfactory. As a rule, there is little that can be done to avoid a fatal termination in the apoplectiform type, in which the patient develops sudden and profound symptoms of intracranial hemorrhage. When symptoms are less severe, with evidence of meningeal bleeding or minor focal signs, transfusion and splenectomy may be considered. In several of our patients previous transfusions did not prevent the occurrence of intracranial hemorrhage. Splenectomy was apparently an important factor in the recovery of one patient in whom intracranial bleeding had occurred. It is to be borne in mind that

splenectomy is attended by a very definite risk and that in most types of secondary purpura as well as in some cases of idiopathic purpura hemorrhagica, splenectomy is not effective in controlling the hemorrhagic phenomena.

Conclusions

 Intracranial hemorrhage is the most common cause of death in hemorrhagica.

2. In our series of cases, seven of ten fatalities were due to intracranial bleeding. The clinical and pathologic findings in five autopsied patients are reported.

3. In one patient with intracranial bleeding due to idiopathic purpura hemorrhagica, splenectomy was followed by recovery. STRONG MEMORIAL HOSPITAL

"Statistical Studies of 3000 cases of Chronic Angiocholecystitis," by M. E. Binet, M.D., President, Medical Society of Vichy, Vichy, France.

These lectures will be held on Tuesday evening, January 28th, at 8:30 P.M. at The New York Academy of Medicine, 2 East 103rd Street at Fifth Ave., New York.

The American Board of Opthalmology announces that its 1936 examinations will be held in Kansas City on May 11, at the time of the meeting of the A.M.A., and in New York City in October, at the time of the meeting of the American Academy, All applications and case reports must be filed at least sixty days before date of examination. For information, syllabuses and application forms write at once to Dr. Thomas D. Allen, Assistant Secretary, 122 South Michigan Ave., Chicago, Ill.

A MARTYR TO SCIENCE

On Christmas Day the U. S. Public Health Service recorded on its special honor roll its first woman laboratory technician to die in the line of disease-research duty-Anna Pabst, 39.

Her life was the sixth in the last decade sacrificed to scientific endeavor in the serv-

Miss Pabst was injecting meningitis serum into an animal Dec. 17 in the National Institute of Health laboratories; it moved suddenly, causing some of the culture to squirt in her eye. Although the eye was promptly cleansed, Miss Pabst was stricken with meningitis Dec. 21, while doing Christmas shopping, and died Christmas night in the Emergency Hospital in Washington.

S.I MEDICAL COLLEGE,

THE PROSTATIC PROBLEM

Present Status

HENRY G. BUGBEE, M.D., New York City

The past few years have been momentous ones in the field of prostatic surgery. To those young in this specialty it may appear that an entirely new era has been ushered in with the present wave of transurethral surgery; while, to those who have been active in this field even for the past twenty-five years, the present enthusiasm represents a high state of efficiency founded upon a clarification of underlying principles long recognized, to which has been added the mechanical perfection of instruments, both elements being the result of a slow process of evolution dating back over many decades.

To even begin to cover the subject of the present status of this important problem and lead up to it in a logical manner is quite impossible in the time allotted for this paper, and I shall, therefore, touch upon only a few of the most out-

standing phases.

The frequency with which prostatic pathology is encountered, either in the form of infection, hypertrophy, or neoplasm, the almost inseparable manner in which this ensemble is often present, and the relationship which one or all bear to vesical neck obstruction, renders this subject vital not only to urologists, but to those engaged in all branches of medicine.

The etiology of vasical neck obstruction has always been a subject for profound thought and much discussion. Today there are many hypotheses as to the cause of this exceedingly common phenomenon, but their multiplicity indicates a lack of specific knowledge. That congestion, infection, hyperplasia, neoplasm, senility, and endocrine imbalance must be considered in this regard seems necessary; and the frequency with which all of these elements are apparently involved in a given case renders it impossible to give one factor as of prime importance in considering any large group of cases.

In following a large series of cases over a period of years, I am convinced that infection plays an important role in the etiology of vesical neck obstruction. In this connection, the seminal vesicles play quite as important a part as does the prostate, infections of the vesicles (venereal or pyogenic in origin) often predominating, periprostatitis and perivesiculitis being commonly present, and the individual structures difficult to differentiate. The intimacy of the relation of the vesicles to the trigone, the ready involvement of the submucous glands of the posterior urethra and trigone in this infection, resulting in fibrosis.

Local congestion has always been recognized as a predisposing factor to hyperplasia and neoplastic changes. Continence incident to infection, continence of middle or past middle life leads very definitely to congestion, and is an element which may be elicited from the history in a large percentage of cases of prostatic

hypertrophy.

The histologic study of prostates removed at operation has shown the presence of a definite infection in many instances. Especially has this been true of pieces of tissue removed by resection, many in the early stages of vesical neck obstruction. These same microscopic sections have often revealed, as reported by the pathologist, the presence of hypertrophy as well. Following bladder drainage, a rapid recrudescence in the size of the prostate frequently takes place, revealing the fact that what appeared to be a large hypertrophy with obstruction was actually a congestion. The same phenomenon has been noted following punch operations, with the removal of a comparatively small amount of tissue.

Studies recently carried out by Lower and his associates at the Cleveland Clinic have emphasized the element of endocrine imbalance in the etiology of prostatic hypertrophy, their experiments suggesting a connection between the incidence of prostatic hypertrophy and the influence of the secretion of the hypophysis. Not only do they believe that they have

demonstrated that the secretion of the hypophysis stimulates the output of the testicular hormone "androtin," which in turn results in prostatic hyperplasia, but a second testicular hormone which they have termed "inhibin" is thought to have inhibiting properties over the hypophysis. . The applicability of these data to man is now being made. Recently, cases treated by the administration of inhibin were exhibited at their clinic, the clinical evidence indicating that these patients who had been suffering from prostatic enlargement with residual urine were symptomatically improved and the prostate in each instance was reduced in size.

Teem of the Mayo Clinic has recently carried out an investigation for the purpose of correlating the size of the prostate gland with the microscopic findings in the testis in a large number of postmortem examinations. Of 504 cases, the prostate was found to be normal in 301, hypertrophic in 189, and atrophic in 14. He made the following conclusions:

(1) The average size of the prostate gland progressively increases from birth to old age. (2) The histologic appearance of the interstitial cells of the testis strongly points toward the elaboration of an internal secretion. (3) The tendency for the number of interstitial cells to decrease as the size of the prostate gland increases makes it probable that this secretion is in the nature of an antihormone. (4) Evidence is presented pointing toward the seminiferous tubules as the possible source of the male sex hormone.

Braasch, in discussing this work, observed that the absence of any convincing evidence of increased function in the interstitial cells of the testis, or of diminished function in the tubules during the period of prostatic hyperplasia, gives only negative evidence as to their functional capacity in the secretion of autocoids.

Further applicability of such data to the treatment of clinical cases is being made, and the results will be awaited with

keen interest.

The fear of a radical operation often deterred men of middle life, presenting the earliest symptoms of vesical neck obstruction, from consulting the urologist. The possibility of relieving obstruction in its earlier stages, through less radical procedures, is now resulting in a change of front on the part of both patients and

physicians; more patients are being seen at a time, when, with an elimination of infection, or a reduction in local congestion, a relief of the symptoms frequently results; or, a less radical operation proves to be sufficient to insure a restoration of function, and gives a reasonable assurance of a permanent cure.

A clarification of the pathology of the urinary tract, and a better understanding of the relationship of such pathology to the body as a whole has been personified in the study of prostatic obstruction, a condition once regarded as a localized lesion now being recognized as a cause of far-reaching changes throughout the body. Back pressure upon the kidneys is known to result in a progressive loss of kidney function; an increase in blood pressure and circulatory changes often of a severe grade, with eventually an impairment of practically every body function. When, as invariably occurs, infection is added to this ensemble, sepsis steps in to lower the resistance of the patient and speed up the changes above enumerated.

Such a conception of the pathological syndrome of prostatic obstruction, plus the realization that we were dealing with a disease of advanced years, made it apparent that such patients were exceedingly poor surgical risks, and, if visualized purely from the operative standpoint, a high mortality might be expected.

Kidney function tests, when correlated with the clinical picture, made it possible to obtain an accurate estimate of the variations of renal function which followed the relief of kidney back pressure, and demonstrated the necessity in all cases, of stabilizing kidney function before considering any type of operation for the relief of prostatic obstruction.

The circulatory system became the object of painstaking studies, valuable information being acquired through electrocardiograms and observations of blood pressure. The importance of reducing urinary infection through increased body elimination, catheter drainage, and establishing an immunity on the part of the patient, also became apparent.

With the recognition of the necessity of complete stabilization of the patient before attempting operation, attention became focused upon the technic of prostatectomy, modifications being instituted which would minimize the complications of sepsis, uremia, and hemorrhage, also postoperative incontinence, and fistula.

With these points in mind, the technic of perineal prostatectomy was perfected, the possible advantages over suprapubic operation as then carried out, of better drainage, control of hemorrhage, less shock than associated with abdominal operation, less tendency to uremia, and a lower mortality were stressed by its adherents. The frequent occurrence, however, of incontinence, especially in the hands of those of limited experience, was apparent; and, although adhered to by a few operators, even to the present time, the perineal operation became supplanted by suprapubic prostatectomy as the operation of choice by most urologists, the functional results in the latter operation being more satisfactory in the hands of the majority.

The fact that postoperative reaction was often severe, even after a period of stabilization preliminary to suprapubic prostatectomy, suggested the advisability of carrying out this operation in two stages, the first step being a suprapubic drainage of the bladder, the prostate being removed as a second step (the enucleation being carried out under regional anesthesia and entailing a very slight risk).

The amount of time required to prepare patients under catheter drainage, and again after cystostomy, varied with each individual, a point which could only be ascertained by observing the clinical picture and employing kidney functional tests, the most accurate of which was found to be the rate of excretion of phenolsulphonephthalein. Following such preparation, patients were operated at the height of their functional renal capacity. at a time when infection had been reduced through sufficiently long bladder drainage and an acquired immunity. Hemorrhage then became a rare complication, congestion of the prostate and vesical neck being greatly reduced by the relief of urinary pressure and diminished infection. Bleeding at and subsequent to operation was readily controlled by pressure, and the mortality incident to suprapubic prostatectomy, when executed in this manner, compared favorably with that of perineal prostatectomy; a mortality lower than

that attained in any other class of similar surgical risks. The functional results were excellent, and, furthermore, the frequent occurrence of associated bladder lesions, embracing tumors, diverticulae, and calculi, which could be dealt with at the primary operation, was another strong argument in favor of the two-stage suprapubic operation.

These two methods of prostatectomy, quite different in their technical execution, but based upon the same broad conception of the pathology, underlying surgical principles, and meticulous after-care, have survived to the present time; and, in certain types of hypertrophy, especially well-marked involvement of all the lobes, (particularly of the soft vascular variety), extensive lateral lobe enlargements, or those in which there is a suspicion of malignancy in an otherwise benign hypertrophy, they will not be supplanted by a less radical procedure until, by this latter, equally complete and permanent restoration of function can be assured.

In the type of obstruction due to fibrosis of the prostate and vesical neck, the so-called "median bar obstruction," also obstruction due to hypertrophy limited to the posterior commissure of the prostate, the subcervical gland of Albarran, and the rare hypertrophy of the anterior commissure, as well as an early hypertrophy of a combination of these groups of glands, also early lateral enlargement; a group of cases characterized symptomatically by frequency, diminution in the urinary stream, and often with no residual, or a residual of from one to four ounces, one formerly hesitated to advise prostatectomy.

With these particular types of cases in mind, efforts have been made to relieve the obstruction by excising, transurethrally, a sufficient amount of prostate or of fibrous tissue to completely free the vesical neck. Thus a reversion to the earliest operative procedures for the relief of prostatic obstruction has taken place, and the first conceptions of the possibility of removing obstruction by endoscopic means have been incorporated in modern cystoscopes and endoscopes. The evolution in the development of these instruments has been accompanied by a perfection in generators of electrical cutting and coagulating currents; and as a result we have our present armamentarium in

its high state of utility.

It is not my desire to delve into the history of the development of these instruments, Gutierrez having made a most comprehensive review of the evolution of transurethral surgery in the recent "History of Urology," in which it was interesting to note that the name connected with a certain method of procedure was more often that of the one who popularized it, rather than of the originator of the method. The following notes, however, seem to point to definite periods of transition:

Everard Home, in 1806, first called attention to the presence of a third prostatic lobe which he suggested as giving rise to a valve-like obstruction—the so-called median

lobe hypertrophy.

Guthrie, in 1834, described non-prostatic obstruction of the vesical neck, establishing a differentiation between hypertrophy of the glandular tissue of the median lobe and the "bar at the neck of the bladder," for the relief of which he devised an instrument consisting of a metal tube curved like a No. 20 F. prostatic catheter, carrying at its extremity a small concealed knife, which was made, by means of a spring, to project at the sides, or end, or both.

Mercier followed, bringing out instruments which incorporated the conception of Guthrie,

In 1874, Bottini introduced his galvanocautery, designed not merely to eradicate the small bar obstructions as Mercier had done with his instrument, but capable of producing a deep destruction of lobe hypertrophies.

Albarran, at the turn of the century, gave a new conception of prostatic hypertrophy, describing subcervical glands of the bladder week which could undergo hypertrophy independent of prostatic hypertrophy, and give rise to the same urinary symptoms. With the inception of modern cystoscopes and urethroscopes, direct observation of these conditions became possible.

In 1909, Young introduced the punch operation, a first report of cases operated in this manner being made by him in 1912, and Caulk added heat to the cutting blade to act as an electrocautery for the control

of hemorrhage.

The idea suggested by Beer, in 1910, of destroying bladder tumors by fulguration, was applied by the writer, in 1911, for the destruction of obstructing prostatic tissue. The first eleven cases treated between 1911 and 1913 were reported in 1913; and sub-

sequent series of cases were reported in 1914 and 1917, seventy-six cases being treated in this manner.

Not, however, until generators producing high frequency currents of sufficient potentiality to make it possible, while operating under water, to cut through even the most resistant tissue, and, at the same time, to congulate bleeding points, and the ingenuity of cystoscope manufacturers produced an endoscope through which such currents could be utilized under clear vision, without shortcircuiting, did such operative manipulations become practical and generally adopted. The names of Stern, Davis, and McCarthy have been closely associated with the recent development of this latter type of instrument.

During the early days of the development of punches and endoscopes, the struggle to establish priority in modifications of instruments, high pressure salesmanship in marketing the various instruments and high frequency generators, and arguments as to which type of apparatus and method of operation was most efficacious, assumed such proportions that the real questions at stake—applicability of the method, technic of operation, complications and results—were often forced into the background. During the past year, attention has been more closely focused upon the real issues connected with this intensely interesting surgical field.

When any new operative technic is introduced or popularized, there is an inclination on the part of operators incompetent as regards experience, knowledge, and technical skill, to apply it indiscriminately, and to enthusiastically proclaim its virtues, before allowing sufficient time to clapse to acquire a true perspective, thus comparing progress with end results obtained by older and thoroughly tried methods.

Such a large proportion of men at middle life and after (probably one in five) suffer from some degree of prostatic obstruction, that the thought of obtaining relief without submitting to an open operation has a strong appeal. Many are willing to seek advice with this possibility in mind, and pressure is often brought to bear upon the urologist, by patients, to adopt this method of procedure in all cases. Furthermore, urologists with in-

sufficient surgical training have taken up resection with alacrity, not realizing that more technical skill and a better knowledge of the anatomy and pathology of the deep urethra and vesical neck are necessary to successfully accomplish resections, than were often required in prostatectomy.

As would be expected, complications ensued, poor results were not infrequent, and mortalities resulted. We are only now arriving at a position from which we can begin to make a survey of the situation.

Whether one employ one of the socalled punch instruments, by which pieces of obstructing fibrous tissue or prostate are punched out under direct vision and the bleeding points controlled by diathermy, or a resectoscope, using a mechanically controlled wire loop, by which means cylinders of tissue are resected, as the loop under clear vision is drawn through the obstructing prostate, a coagulating current then being substituted for the cutting current to control the bleeding, the results are probably the same in equally skillful hands.

One might say that resection is the ideal procedure when the obstruction is caused by a minimum amount of tissue, and least desirable in cases of large hypertrophies—whether of one or all lobes. The objective, whatever type of operation is employed, is to completely and permanently remove the obstruction, control hemorrhage and infection, at the same

time preventing uremia.

When infection is pronounced and the prostate is large, soft, and vascular, hemorrhage may be a troublesome complication of resection. There may be extensive sloughing, and several resections may be necessary. Under these conditions, a two-stage prostatectomy seems (with our present knowledge) safer, more complete, and the result is permanent. Furthermore, carcinoma is occasionally found on pathological section in a certain percentage of large hypertrophies-nodules which could not be detected on palpation before operation, being present in the center of the lateral lobes, as in seven cases reported by the writer in 1928, and in six cases encountered since that time, only one of which has since died.

If only one lobe, or sections of large

large hypertrophies, remaining lobes or sections of prostatic tissue may subsequently drop into the vesical orifice and give rise to obstruction. If resection is attempted in these extensive hypertrophies, large portions of the gland should be removed. The permanency of the result in any case depends upon the thoroughness of the resection, and in this type of cases can only be ascertained by observations extending over a period of years.

In outlining the treatment for prostatic obstruction, each case should be advised according to the individual pathology pre-There are a certain number of cases that may be relieved by local treat-Others should undergo a prostatectomy; while probably seventy-five per cent may be cured by resection. If patients are prepared for operation and every precaution is observed to combat the complications of hemorrhage, infection and uremia, the mortality resulting from prostatectomy, or from resection, in the hands of one equally skillful in both types of operation, should be just about the same. Permanency of cure should be assured in radical operation.

Some of the local complications of resection that have been reported have been hemorrhage, burning through the bladder, injury to the external sphincter with resulting incontinence, extensive infection, gangrene of the bladder, urethral stricture, and a recurrence of the obstruction. These complications are largely the results of incompetent operators and improper selection of cases. Similar complications may also be cited following prostatectomy when carried out by unskilled surgeons employing poor judgment and improper

surgical technic.

Patients should be prepared for resection as for prostatectomy; the operation should be carried out under caudal or spinal anesthesia; the vasa should be ligated; the urethra slowly dilated to a sufficient size to accommodate a resectoscope or punch without inflicting traumatism in its passage; cutting should be limited to the area posterior to the verumontanum, and all obstructing tissue should be removed. If the wire loop is employed, a current should be available which will cut cleanly without causing too deep a slough, and one should also

have at hand a coagulating current with which to control hemorrhage, a step that should be carried out thoroughly before completing the operation. Catheter dramage is necessary after operation, until the urine is free of blood, which should be in from twenty-four to forty cight hours. If the patient does not empty the blad der, longer draininge may be necessary, or a repetition of the resection required—all patients being kept under observation and local treatment until a satisfactory function is assured and infection has been controlled.

In ninety per cent of the cases so operated, if properly selected, the immediate results from resection will be highly satisfactory, in many, brilliant, while, in about ten per cent, subsequent treatment will be required to free the patient of infection, and, in a certain number, a second resce Patients undergoing resection are, as a rule, hospitalized for a much shorter time than is required for prostatectomy, with a corresponding economic saving There is very little shock attendant upon the operation, and one does not hesitate to advise a resection in early cases and in very poor surgical risks, when one might hesitate to advise a prostatectomy In one of the writer's cases, a man of ninety three, the patient was out of bed the day following resection

In 1932, the writer, in a paper on the Operative Relief of Prostatic Obstruc tion", reported a series of 233 prostatectomies over a period of eight years, with two mortalities-the 126th and 201st Since April, 1932, there have been twenty seven prostatectomies with no mortality, and 167 resections with two mortalities, of the latter, one was due to septic pneumonia four weeks after opera tion, with complete restoration of blad der function, necropsy in this case showing no obstruction or slough at the vesical neck, but an advanced bilateral pyonephrosis, and bronchopneumonia The second mortality was due to pulmonary embolus seven days after operation, with bladder function restored Both were exceedingly poor surgical risks. There has been no recurrence of obstruction in any of the cases of prostatectomy, and no late recurrence in any of the resection cases

Included in the latter are twenty-three instances of carcinoma with retention. In

every case, function was re-established and great comfort derived from the operation. Two cases have since died of metastasis, twelve and fourteen months after operation.

Resection has been carried out in all types of cases of prostatic obstruction The first few cases of general hypertrophy were operated upon as a trial of the method, and, while no serious complications were encountered, subsequent cases of hypertrophy of an advanced degree involving lateral lobes and commissures, both lateral lobes, or one very large lobe, have by preference been subjected to If large hypertrophies prostatectomy are to be removed by resection, repeated operations are preferable to one prolonged operation, and I still believe that in these cases prostatectomy is the operation of choice

In but one case was postoperative hemorrhage following resection severe enough to necessitate returning the patient to the operating room for further cruterization, and there have been no secondary or delayed hemorrhages, other than a slight bleeding in a few instances, from ten days to three weeks after operation

In many cases there is an infection of the prostate and the seminal vesicles with the obstruction. This infection will occasionally continue after resection and require postoperative care. Infection is the most annoying complication of resection. With the vasa ligated, epididyimits does not occur. Bladder function may be satisfactory at once, but, in some cases, may be delayed, while a second resection may be necessary in a small percentage of cases. Progressive improvement is usually noted even though a slight residual (30 to 60 cc) may be present immediately after operation.

Unquestionably, in resection, a method of procedure has been added to the operative management of prostatic obstruction, which, with its assurance of relief in early cases, its relatively short period of incidental morbidity, and extremely low mortality, will encourage the earliest cases to seek relief before extensive damage has resulted not only to the urmary tract, but to various body functions

In those cases of median bar obstruction, of moderate commissural or subcervical hypertrophies, as well as early small hypertrophies of all lobes, and in carcinoma with retention, resection should give most gratifying results when carried out upon patients carefully prepared as for prostatectomy, and operated upon by one skilled in this branch of surgery, adopting all precautions against hemorrhage and sepsis.

Three cases of median bar obstruction presenting a marked fibrosis of the vesical neck with large amounts of residual urine (35, 58, and 62 ounces) were operated upon in 1924, 1926, and 1930. In each instance, suprapubic drainage was followed by a punch operation which, at that time was thought to be complete. Histologic sections of the tissue removed showed fibrosis with small areas of prostatic hypertrophy. These patients all had residual urine following operation, varying up to seven ounces, and although all were free from catheter life, infection con-Within the past two months, I have done a resection on all three of these cases. In each, no prostatic enlargement could be detected. The tissue removed showed (histologically) as before, a fibrosis, also small areas of prostatic hypertrophy. The cloudy urine has markedly cleared, and there is no frequency or dysuria.

These three cases represent a type in which formerly it has been most difficult to obtain a satisfactory functional result. In the presence of extreme sclerosis of the vesical neck with large amounts of residual, seldom has bladder function been completely restored subsequent to the various open operations that have been employed, or punch operations as formerly carried out. Postoperative retention has been ascribed to atony of the bladder muscle.

Crabtree suggested complete perineal prostatectomy as a cure, anastomosing the severed urethra to the bladder neck. However, a thorough resection of the constricted vesical neck, under clear vision, seems to be an ideal procedure in such cases.

Comparisons of the mortality and morbidity associated with prostatectomy and endoscopic resection can only be made when these operations are carried out upon exactly parallel cases. When one reads reports from certain clinics of series of several hundred cases operated by resection, with no mortality and a very low morbidity, one must realize that many of these cases (probably fifty per cent) are incipient ones, occurring in comparatively young men, excellent surgical risks, presenting few complications—cases which would not have been considered as candidates for prostatectomy, but would formerly have been given local treatment. In this group of cases the mortality should be practically nil and the morbidity low.

This is not an argument against resection; to the contrary, it is in this type of case that resection bids fair to occupy a very important role, by removing the cause of the symptoms in its incipiency before permanent damage has taken place. However, these cases cannot be set up as an argument for resection as opposed

to prostatectomy, in every case.

If, however, one compares mortality, morbidity, and possible complications incident to resection or prostatectomy, when carried out for the relief of prostatic obstruction caused by large vascular hypertrophies, I believe that in the hands of those equally skilled in both operations, the results will vary but slightly in these respects; on the other hand, when the large prostate *is* completely removed, function is restored, is permanent, and infection seldom remains to be a cause for postoperative symptoms.

'The problems involved in the relief of prostatic obstruction are manifold. They require an ability on the part of the urologist to individualize patients; to patiently treat those not requiring operation; to recognize the necessity of thoroughly preparing patients for operation, and to select, without prejudice, the operation best adapted to the individual case. Technical skill in carrying out the operative procedures is a necessity, and conscientious after-care should be continued until the patient has completely recovered.

Patients should no longer hesitate to seek advice with the onset of the first symptoms of vesical neck obstruction, at a time when the cause for such symptoms may possibly be removed either by treatment, or by an operation which involves a slight morbidity and gives an assurance of future comfort. They should also realize that radical operation may, in certain instances, be the more conservative plan of action.

DEAFNESS

Diagnosis Based Upon Functional Testing

CLANTON M BROWN, MD, Buffalo

The justification for attempting to prepare a paper upon so well-known a theme must arise from a desire to present something new or a wish to revive interest in the subject. This latter is my hope Among the younger men and also among many of the older ones, there has been a tendency, either to ignore functional ear testing, or to do it indifferently.

I have been unable to determine whether this situation is the result of poor teaching or due to the feeling that nothing can be done to help those who have a hearing fault (excepting those accounted for by cerumen in the external canal). I believe that both poor teaching and poor prognosis are at fault Certainly, we are not liable, except by chance, to benefit those we think we cannot help. If we do not make careful and accurate functional tests we cannot locate the aural lesion, and if not properly located, it cannot be properly treated.

Prevention plays an exceedingly important part in modern medicine How many of us are careful to follow up with functional testing, until no further improvement can be obtained, our cases of acute catarrhal otitis media with serous exudate, or those of acute suppurative ofitis media, or our cases of acute mastoiditis? Is it not true that many of our cases of deafness give a history of one or the other of these causes which was not followed through with functional tests? Do you not believe that many of these cases of hearing fault could have been avoided by proper follow-up exammations and treatment?

As otologists we have had a wonderful heritage handed down to us by the works and teachings of Von Helmholtz, Von Troltsch, Politzer, Bezold, and many others Aside from their marvelous knowledge of anatomy and pathology and their wide experience, it has always seemed to me that much of their work centered around functional testing. We would do well to follow in their footsteps

In a report by Dr Sonnenschein, chairman of the committee appointed by the Academy of Ophthalmology and Otolaryngology, on standardization of tuning forks and hearing tests, he states

Considerable work has been done with Audiomaters of various types in the past few years. While these instruments are of great value in furnishing Audiograms which give a graphic idea of the state of hearing of the individual, still we feel that they are merely adjuncts to, and cannot as yet replace, the voice, tuning forks, whistles and monocord in functional testing

It is not my purpose in any way to deprecate the use of the audiometer, for I do feel it serves a very useful purpose and that it does give us a fair test as to the quantitative hearing. There are points in diagnosis, however, which are of far greater importance than quantitative hearing If deafness exists, we wish to know what part of the hearing apparatus is at fault, also, we want to know the character of the lesion, as well as the primary cause or the etiological factor. The amount of the hearing is of interest to the patient, and incidentally, to us as otologists, but principally as a measuring stick to determine the changes that come about as the result of the lesson or the improvement that occurs as the result of treatment In compensation cases also, this percentage loss of hearing as shown by the Audiogram is important But the quantitative test does not help us materially in the diagnosis or prognosis of the case

As otologists we are consulted for the purpose of determining if the hearing may be improved or prevented from becoming worse. To do this we must know the location of the hearing fault and it is here that functional testing enters to help us

Bezold states that hearing tests are just as lighly developed and therefore equally as complicated as the functional tests of the eye. He also states we are able to analyze with the continuous series of tuning-forks, the very elements of the organ of hearing. We can diagnose

changes and localize loss of functions in the inner ear just as accurately as we can search the fundus of the eye with the obtthalmoscope.

It is customary to divide the hearing function into a sound conducting and a sound receiving apparatus. The sound conducting apparatus is that part of the ear which is external to the oval window, and includes the footplate of the stapes and the ligamentum annulare, and its function is to transmit the large, slow, and weak movements which are produced in the air by the lower half of the sound scale, smaller but stronger to the column of fluid in the labyrinth. When we have an interference of the sound conducting mechanism, we have in particular, an interference in the lower part of the sound scale. The sound receiving apparatus consists of that part of hearing system internal to the oval window, and its function is the perception of sound. It is possible by functional testing, to determine which one of these two apparatuses is at fault, or to determine if both are at fault. Other tests help us in determining which part of each apparatus is at fault.

Two major difficulties interfere with perfect functional testing; inaccuracy and lack of uniformity of tuning-forks, and noisy examining rooms. Inaccuracy is partly due to unscientific methods of manufacture; it may also be due to corrosion of the metal itself, interfering or changing the tone of the fork. Weighting of the prongs has largely overcome overtones. The ideal fork is made of one piece of rustless metal, light in weight, but accurate as to the number of vibrations. The magnesium alloy forks made by the Riverbank Instrument Company fulfill these requirements. Previously the best forks were those made by Edelman of Munich, and known as the Bezold Edelman forks.

The overtones in these forks have been largely taken care of by making the first overtone the same pitch as the plate tone. Forks should not be electroplated as this interferes with the vibration, and as the plating separates, as it will in time, we again have an inaccuracy of vibrations.

The second objection, that of eliminating the extraneous noises or the production of a sound proof room, can be accom-

plished only by the expenditure of from one to two thousand dollars. However, the building of a soundproof cabinet, large enough and complete for tuning fork examinations, can be accomplished at a small initial expense of one or two hundred dollars.

The manner of using the forks is important. It is better, in testing with forks for the patient's eyes to be closed. In testing for bone conduction, the pressure of the fork should be as nearly equal as possible at all times. There should be nothing intervening between the fork and the skin surface, and as nearly as possible the same point on the skull should be used for the same test in each case. In air conduction testing the fork should be suspended from a point as near the end of the stem as possible, should be held with the broad part of the prong directed to the auditory canal and at a point as near the canal as possible, without in any way touching the skin or hair.

The element of fatigue of the auditory nerve from too constant application of the fork must be avoided if we are to obtain accurate results. To avoid this fatigue the fork should be removed about every two or three seconds and kept away for about the same length of time and then returned. This element of fatigue of the auditory nerve applies to all forms of tuning-fork tests. The manner of agitating the fork is also important.

The methods usually employed are the striking of the lower note forks against the ball of the thumb, and those of the higher vibrations with a small rubber mallet. The examiner can usually tell, by his own ear, if there are any overtones produced, and the testing should be begun when these overtones cease.

The length of time the vibrations are heard is important especially in the Rinné test and should be recorded.

For ordinary office practice a quite sufficient armamentarium of forks consists of two small A1 forks, one small C4, one large C1 and a large A fork. The small C4 and small A1 forks give us a very fair test of the high notes while the large C1 fork tells us fairly accurately about the low notes. I use the large A fork for Schwabach, Gelle, Weber, and Politzer; the small A1 forks for Rinné and Stenger.

the acute stage of multiple sclerosis and pointed out that intermediary forms occur frequently. Furthermore, pathological examination of chronic cases reveals frequently the presence of some "early patches" scattered among the foci of dense sclerosis. A few years later (1913) Frankel and Jakob³² added new evidence to Marburg's conception on the basis of their own cases. They felt that the differences between acute and chronic multiple sclerosis are precisely those which separate a chronic from an acute condition, namely, "differences in intensity and tempo of the process." Oppenheim³³ (1914) set the seal of his authority upon Marburg's conceptions and since then numerous clinical pathological reports have substantiated the existence of an acute form of multiple sclerosis: Jakob10 (1916), Spiller³⁴ (1919), Ronne and Wimmer,³⁵ Creutzfeld³⁶ (1923), Marquezy³⁷ (1927), Pette^{38, 39, 40} (1928), Guillain and Alajouanine41 (1928), Cour-(1930), Ley and Bogaert¹³ (1931), Toyama44 (1931), Reuter and Gaupp45 (1932), Denime,46 Austregesilo47 (1933), Urechia and Elekes48 (1933),

Obviously as Pette noted, it is not correct in acute cases to speak of "sclerosis" in the anatomical sense of the word, since a sclerotic overgrowth of glia fibrils does not occur. But such a sclerosis implies a previous lesion which constitutes precisely the pathological basis of the acute form of multiple sclerosis. The existence of such a condition seems therefore strongly established, though not of a common occurrence. In more frequent instances the acute form constitutes either the beginning or episodical relapses occurring in typical chronic cases. All gradations between acute and chronic forms may be observed clinically. Pathologically variations involve the fat products which are more or less abundant and the glia fibrillary overgrowth which is more or less intense.

In our case, multiple sclerosis was not thought out as a clinical diagnosis because of the absence of the main symptoms of this disease. Probably also some of the findings which would have been interpreted in favor of multiple sclerosis could not be evaluated because the patient was in poor condition and unable to cooperate.

From the pathological standpoint, however, when we consider the main characteristic of the small patches, namely destruction of myelin sheaths, with relative integrity of the axis cylinders, severe cellular glia reaction, perivascular infiltration, distribution of the foci in the gray and white matter with preference for the latter, diffuse involvement of the medulla, pons and midbrain, we might be justified in considering such lesions as "early patches" of acute multiple sclerosis.

4. A last diagnostic possibility to be taken into consideration in our case is "acute disseminated encephalomyelitis." The occurrence of such acute forms has long been recognized (Westphal, Strumpell, Oppenheim, P. Marie) and in 1912 a complete study was offered by Anton and Wohlwill.10 It is, however, within the last few years that numerous cases of acute spontaneous encephalomyelitis have occurred in various countries. Pette 39 in Germany, Redlich 50 in Austria, Flatau 51 in Poland, Brain,52,53 and MacAlpine 51 in England, Spiller, 55 Grinker and Bassoe,50 Stout and Kamosh 57 in the United States are among the authors who observed the largest number of cases. The symptomatology is protean. In the spinal type motor weakness of flaccid or spastic type, sensory changes, and sphincter disturbances are common signs. Dysarthria, aphonia, dysphagia, and nystagmus have been repeatedly noted indicating involvement of the brain stem. In the cerebral type the symptomatology supplies mental signs such as confusion, disorientation, delirium, stupor and focal cortical signs such as hemiplegia, hemianopsia, and aphasia Convulsions and meningitic manifestations occur frequently in children. The course is rapid, the appearance of symptoms abrupt, and the mortality low; complete recovery is frequent. In some instances, (MacAlpine). may remain sequelae Recently, Stout and Kamosh,57 reviewing the clinical symptomatology of twentyeight personal cases have stressed the importance of remissive and relapsing features. The pathology of the condition consists of disseminated lesions equally scattered in the gray and white matter of brain and spinal cord. Such lesions, in which myelin and axis cylinder destruction takes place with varying intensity, are generally related to blood vessels.

Perivascular cellular infiltration of the socalled hematogenous type is generally present pointing to the inflammatory nature of the disease.

Difficult questions arise when the relationship between acute multiple sclerosis and acute dissemmated encephalomyelitis is discussed. Are the two conditions separable? If affirmative, upon what criteria? The discordant answers one finds in the recent literature point out at best the difficulty of giving an answer Redheh 50 demes that his cases of acute encephalomyelitis belong to the disseminated sclerosis, although when speaking of differential diagnosis between the two conditions he discusses only clinical differential data. Although recognizing that the two diseases in their acute phases and m their sequelae are quite alike, Mac Alome's suggests that the two conditions differ in their pathological process Prac tically, however, he only gives clinical differential symptoms which are different from those given by Redlich Clinical features such as suddenness and gravity of onset, frequency of psychotic and extrapyramidal symptoms and peculiarities of the evolutions are also stressed by Del-becke and Bogaert * in order to clinically differentiate the two conditions Cournand,42 on the other hand, insists precisely on clinical data to support the identity of acute multiple sclerosis and acute encephalomyelitis Gerstamann 50 and Hallervorden 60 add several pathological features to the differential diagnosis, among them, relation of the patches to blood vessels in acute encephalomyelitis, numerous perivascular infiltrations, involvement of axis cylinders, acute myelin destruction, degenerative forms of protoplasmatic gha

On the other hand, Pette 10 40 in a series of investigations based upon numer ous cases which constitute clinical and pathologic gradations between multiple sclerosis and disseminated en cephalomyelitis (in the sense of Redlich) strongly supports the fundamental identity between the two conditions Basing their conclusions on the pathological findings, other authors including Spatz, at Jakob, Spiller and Marcus, 2 Urechia, Dennine, etc, feel it impossible to consider their cases of acute encephalomyelitis and multiple sclerosis to be other than varie-

ties of the same fundamental process It is difficult therefore to draw definite conclusions from such discordant view-

points

Now what elements does the study of our cases contribute to this discussion? From the histopathological standpoint, we have observed both typical "early patches" of so-called acute multiple selerosis, and also foci showing features which, according to some authors are characteristic for acute encephalomyelitis namely, (a) relation of the foci to blood vessels, (b) involvement of both myelin sheaths and axis cylinders, (c) intense perivascular infiltration

Must we now accept the three last mentioned features as characteristic for acute encephalomy elitis?

(a) In typical cases of multiple sclerosis the relationship of the patches to blood vessels has been a matter of much controversy Among the recent authors, Hassin 62 denies a vascular dependency of the patches and Falkievicz 44 concluding his study of numerous cases, states that "it is a rare occurrence that a true topographical relation exists between focus and blood vessel even in the sense that the focus extends within the area of distribution of the blood vessel occasionally seen occupying the focus" Wohlwill 65 stresses an opposite conception He notes that in the spinal cord there are two types of patches, the wedge-shaped one ind the round one, exactly corresponding to the distribution of the transverse and perpendicular branches of the lateral vessels of the cord In the basal ganglia and centrum ovale the patches appear to begin as perivascular foci and later fuse into irregular areas. In the costex the superficial patches are wedged or arched-shaped corresponding to the areas of supply of the superficial vessel of the cortex Guillain Hallervorden and Spatz confirm such facts In our case, the foci at times coincided or were within the area of distribution of a blood vessel at other times appearing completely independent. Thus this criterion does not seem to be quite decisive in the labeling of the pathological process

(b) Charcot's dogma of the "axo myelinic dissociation" in multiple sclerosis, already shaken by the investigation of Doimkow (1915), Jakob (1923) Marinesco (1924) has been extensively criticized by Jaburek 60 This investigator basing his findings on a systematic study of six chronic cases of multiple sclerosis describes, besides old sclerotic patches with axis cylinders almost intact, patches in which the axis cylinders

undergo severe regressive changes showing irregularity in their impregnation, diffuse or localized swelling and granular disintegration.

Such findings cast, therefore, enough doubt upon the differential value of the involvement of the axis cylinder in acute encephalomyelitis. In our case, foci with intact axis cylinders were found nearby patches in which severe alteration of both myelin sheaths and axis cylinders occurred.

(c) The difficulty of interpreting perivascular infiltrations may be well exemplified by our case. We found, in fact, at times, lymphocytes and plasma cells, i.e., elements of so-called hematogenous origin as the only constituents of the perivascular infiltration. At others, gitter cells were the fundamental elements and at others finally both gitter cells and hematogenous cells were found surrounding the blood vessel.

Is the hematogenous infiltration when present, dependent in our case upon the abnormal products of disintegration of the tissue or is it the expression of the reaction to an infectious agent? In other words, are we dealing here with a symptomatic type of inflammation or with a primary one? The question is easier to put than to resolve. The criteria as given by Jakob,67 Spatz,61 Wohlwill,68 etc., in such instances are merely quantitative, based essentially upon the rather subjective judgment of the amount of hematogenous perivascular changes in comparison to the amount of "Abbau" products. Spielmeyer 69 adds the criterion based upon the time relationship between the two processes, although the evaluation of the "tempo" factor is quite difficult in a pathological examination.

In our case, the intensity of the infiltrations, their occurrence also outside the patches of demyelinization, the disproportion between the severity of the process of demyelinization and the intensity of vascular reaction (marked infiltrations being seen in small patches), are all elements which seem to speak for a primary vascular reaction.

However, a primary vascular reaction is not characteristic of acute encephalomyelitis as in multiple sclerosis. Many recent workers (Siemerling and Raecke, ⁷⁰ Guillain, Pette, ³⁹ Birley and Dudgeon, ⁷¹ Symonds, ⁷² Maeder, ⁷³ have stressed the perivascular infiltration as almost conclusive evidence of the infective nature of multiple sclerosis.

Concluding, pathological features characteristic of diffuse sclerosis, concentric sclerosis, acute multiple sclerosis, and disseminated encephalomyelitis are gathered together in our case. This we feel might constitute a support for the essential identity of the above mentioned demyelinizing processes. In other words such conditions might constitute nosologically a group of processes at times disclosing from a clinical viewpoint poorly defined clinical boundaries but possessing the same fundamental pathology. The similarity of pathological features does not justify, however, the conclusion of an identity of etiological agents. It is probable that different etiologic factors may produce the same pathologic picture, the nervous system reacting in fact but in a limited manner to different agents so that the number of pathological syndromes is forcibly scanty (Spielmeyer). As a matter of fact the experimental pathology has already brought elements of considerable interest to the question of etiology of demyelinizing processes. With different substances such as tetanus toxin (Claude,74 Putmann, Kenna, and Morrison⁷⁵), toxin of Asperigillis fumigatus (Ceni and Besta⁷⁶), peptones (Buscaino77), saponine (Donaggio78), vinila-(Luzzato and Levi79), carbon monoxide (Meyer⁸⁰ and Putnam⁸¹), bile (Weil and Crandall⁸²), potassium cyanide (Ferraro⁸³ and Rubino⁸⁴), it has been possible to determine areas of demyelinization and at times glial reaction that recalls the pathological features of disseminated and of diffuse sclerosis.

In our case, the etiology of the condition could not be determined. A careful search failed to reveal a living agent. We were able to detect a certain amount of Steiner's argentophilic cells. It is difficult as yet to estimate the importance of such a finding. According to Steiner steels are found only in luetic processes of the nervous system and in multiple sclerosis. This has been confirmed by Rogers and Kopeloff. That they are expressions of a spirochetic origin of the process, as Steiner claimed, we have no proof.

The finding of a generalized miliary tuberculosis in our case leads one to the hypothesis that tubercular toxins might have been at the base of the demyelinizing

process These would agree with the concentric aspect of demyelinization which has been recently referred by Hallervorden and Spatz as being due to diffusion of a toxic agent throughout the nervous tissue in accord with physicochemical principles

Summary

1 The authors report a case of acute demyelmizing encephalomyelitis characterized pathologically by a Two large diffuse symmetrical foci of demyelinization in the medullary substance of the cerebral hemispheres, comparable to the diffuse foci described in sclerosis b Several areas of concentric demyelinization, i.e., comparable to the one described in the so-called concentric sclerosis c Numerous small patches of demyelinization scattered throughout the cerebral hemisphere, the basal ganglia, the pons, and the medulla oblongata and comparable to the ones described in acute multiple 4 lerosis

2 The authors stress the importance of the association in their case of clinical and pathological features of diffuse sclerosis, concentric sclerosis, acute multiple sclerosis, and disseminated encephalony clitis

3 A brief account of the opinions of various authors as to the relationship of the above mentioned conditions is given and the belief is expressed that diffuse sclerosis, concentric sclerosis, acute multiple sclerosis, and disseminated encephalomyelitis might constitute a large nosological group with identical underly-

ing clinical and pathological findings

4 The question whether the same etiological factors are at the base of the various conditions mentioned is not ready for solution Some experimental data, however, point to the fact that in the nervous system dıfferent etiological factors may produce pathological changes common to acute encephalomyelitis, multiple sclerosis and diffuse sclerosis

SCIENTIFIC EXHIBIT SPACE

Notice has been received from the Committee on Arrangements for the coming annual meeting of the Medical Society of the State of New York that all available scientific exhibit space has been assigned.

Pictures that are overdrawn are caricatures or cartoons, but we get many a hearty laugh from them, and it is more than likely that Dr. J. P. Warbasse chuckled as he wrote this catalogue of various kinds of doctors in his book on "The Doctor and the Public," published by Paul B. Hoeber. He

"Some doctors come plunging into the chamber of the sick like a fireman about to extinguish a conflagration; they alarm the patient. Some come like a detective looking for a criminal, and give the patient cold creeps. Others enter stealthily like a cat stalking a bird, and are beside the patient and pounce upon the pulse before any one is aware; they fill the patient with a weird sense of the chase. There is a class that come like purring doves, as though they would make love; they are thought nice by sentimental ladies. There are the doctors with the doleful faces, like the hired mourners who follow the catafalque; if the patient is bad they make him worse; if he is not they cause him to smile. A common lot enter like the monologue artist on the vaudeville stage and start a barrage of wisecracks that entertain the nurse and amuse themselves, while the patient waits for business to begin. Then there is the radiant doctor who has studied how to impress himself upon others and fill the room with the effulgent aura of his personality; he impresses only the weak-minded. There is the pompous doctor of the school of hope, who, comes with a strong expression and eyes beaming with glad tidings; he scares the demon of disease, and makes the patient fearful of the size of the doctor's bill. Some doctors enter in a casual way, apparently unconscious of the patient's presence, and talk about the weather or the fire, while the patient longs for succor. The egotistic kind first must tell how busy they are and how little sleep they snatch between the rings of the telephone, how fast they have to drive to reach the outposts of disease, and how extraordinary are the cures they make; these give comfort to some, but mostly to themselves. There is the stumbling lout, whose bag upsets the vase of flowers, and who sets his bulky hulk upon the bed; the patient forgives much in the hope that the doctor is mighty also in healing power. The business-man physician whose manners smack of the marts of trade, smart, abrupt, and dapper, impresses the patient that he is attending a board meeting and wants the minutes read at once; the patient wishes he were more sympathetic. And then comes the doctor of mystery, all quiet and sedate, with soft voice, and furtive words, and sanctimonious manner; the patient, if of the susceptible type, thinks of wonders and of miracles.

"When the patients do well under their administrations, which in nine cases out of ten they do, each of these peculiarities becomes glorified into a healing virtue, and the doctor goes on cultivating his idiosyncrasy. The vast number of highly qualified physicians come under none of these classifications. Most physicians are just plain doctors. They may be tinctured with some of these traits, but not enough to matter. They exemplify good bedside manners. They possess unbanity; it is obvious that they are gentlemen; they do and say the thing that is fitting; they go about their business with dignity, directness, and despatch; it is clear that they have the matter in hand; and then, when they have finished, they say the few words that indicate sympathy and understanding, and quietly take their leave."

OBSERVATIONS OF THE CLINICAL COURSE OF ARTERIOSCLEROTIC AURICULAR FIBRILLATION

Louis Faugeres Bishop, M.D., New York City
and
Louis Faugeres Bishop, Jr., M.D., New York City

A study has been made of sixty-nine patients with fibrillation of apparent arteriosclerotic etiology who had been observed in practice. Some of these have been followed for periods covering from

five to twenty years.

In the selection of this group for study no patient was included where there was any history of symptomatology suggesting rheumatic fever or where there was any clinical evidence of mitral stenosis. Any example of thyroid disease was excluded. In addition a small number was excluded where chest trauma had apparently played a part in the onset of auricular fibrillation. In spite of this, the question arises whether it is better to call this type of fibrillation, "non-rheumatic," rather than arteriosclerotic, as has been mentioned by Cookson 1 and others. (If one uses the term, "non-rheumatic" fibrillation, examples of thyroid disease would have to be included.) All in this small group, however, had some clinical evidence of arteriosclerosis present as shown by observations on the peripheral or retinal vessels.

The diagnosis of auricular fibrillation was confirmed by electrocardiograms in every case; in a large number of cases electrocardiographic observations were repeated over a period of years.

It seemed desirable to further subdivide arteriosclerotic auricular fibrillation into groups associated with and without hypertension. Arbitrarily, those having a diastolic pressure of 100 or over were considered hypertensive. It is wellknown, too, that the measurement of blood pressure in auricular fibrillation is often difficult. In a large number recording blood pressure apparatus was used to check observations made with the mercurial manometer.

The group was further subdivided into those with paroxysmal and chronic fibrillation.

Age. The average age of this group when first seen by us was sixty-one years; the youngest in the series was forty-six, the oldest eighty-five. This did not always correspond to the age of onset as a number had been fibrillating before appearing in the office. Every observer trying to study a group of fibrillating patients has also been. impressed with the difficulty of determining the exact onset of fibrillation.2,3 Although the onset can be noted in a small number, one can only give statistics with regard to fibrillation as determined by the time when the diagnosis was made and confirmed by the electrocardiograph. In those patients in which hypertension was present, of which there were twenty-nine (12 females and 17 males) the average age for both male and female was sixty-two years. In those in which hypertension was not present, of which there were forty (12 females and 28 males), the average age of both sexes was fifty-six years; that of the male, fiftyfour years and of the female, sixty years.

Sex. Of the entire group there were forty-five males and twenty-four females. It does seem to us that arteriosclerotic auricular fibrillation is more frequent in the male though other factors may be taken into consideration.

We found that there were twenty-eight males and twelve females where hypertension was not present. In the hypertensive group there were seventeen males and twelve females. Although there is some difference of opinion in which sex hypertension is found more frequently, most authors state that essential hypertension is more commonly found in the female.⁷

Habitus: Type of Individual. In observing these patients with arteriosclerotic auricular fibrillation a large number were obese. Taking the group as a whole, forty-three (32 males and 11 females) were obese out of a total of sixty-nine. The high percentage of patients with obesity in heart disease in general accounts for the large number of obese patients with auricular fibrillation.

Symptomatology. Practically all these patients (either hypertensive or nonhypertensive) with auricular fibrillation complained of some rather definite symptoms at

the time they were first observed. The most prominent symptom noted by us in observing these patients with auricular fibrillation was dyspnea on exertion. There were fitty-two of our group of sixty-nine who complained of this symptom at some time or other while we were studying their condition.

It is easy to conceive that this group of arteriosclerotic auricular fibrillation may often be asymptomatic; yet in the observation of these cases, this did not seem to be true. In a number, symptoms were not produced except by some reason which in all probability increased the ventricular rate.

It has been noted by many observing the course of auricular fibrillation that patients quite frequently describe a consciousness of their irregular hearts. In our observations some of the following rather dramatic remarks were made by these patients: "If I overdo, my heart balks," or, "I feel as if my heart is running over if I exert myself." The complaint of fatigue without exertion was often present. We also noted that in a large number of these patients associated gastrointestinal complaints were present, for example: flatulence and constipation. In an occasional case, where we had a definite history of the onset, symptomatology closely resembled that of paroxysmal tachycardia.

Although it is commonly stated that cardiac pain is frequently absent in patients with auricular fibrillation, the following facts were noted in our group of patients:

In the entire group we were able to ascertain that there were eight where the pain was present and definitely related to exertion. We excluded what might be termed vague discomfort in the chest, and each of these eight patients had definite pain which might well be considered a typically anginal syndrome. One hypertensive male had definite anginal pain in attacks, another hypertensive female had pain on exertion and emotional strain, and yet another in the hypertensive group, a female, had pain also on exertion. Two nonhypertensive males had pain on exertion, one nonhypertensive male had pain on walking, one nonhypertensive female (paroxysmal type) had definite pain in the throat accompanying palpitation, and yet another nonhypertensive female could not walk against the wind without precordial pain.

If the symptomatology of patients with fibrillation is more carefully analyzed, it will be found that pain is more frequently present than usually supposed heretofore.

Electrocardiographic Observations

These electrocardiograms were taken

from 1917 to 1934, inclusive, and revealed the following facts:

T Wave. We did not consider observations of the T wave of any importance on account of the probability of deformity by digitalis, together with difficulty of interpretation on account of the superimposed fibrillary waves.

QRS Aberrant Ventricular Complexes. In four cases aberrant ventricular complexes were noted, the details of which are as follows: One left bundle branch block, two where the QRS exceeded 0.1 of a second, and one where the QRS was widened and of low amplitude. There were therefore two cases where there was definite bundle branch block associated with auricular fibrillation and one case of so-called arborization block.

Premature Contractions. In the sixty-nine cases studied premature contractions were present in eight hypertensive cases and thirteen nonhypertensive cases. Here again we can only be very guarded as to their significance on account of the fact that the vast majority of these patients received digitalis.

Amplitude of Fibrillation Waves. It has been stated that fibrillary waves wherever noted in the limb leads are smaller in the nonrheumatic than in the rheumatic group. Our belief is that the fibrillary waves noted in auricular fibrillation (nonrheumatic) are of smaller amplitude than in rheumatic fibrillation. In this nonrheumatic group, we merely noted whether the fibrillation appeared to be fine or coarse; there were briefly; coarse, twenty; fine, forty-nine.

Digitalis. Of the entire group, sixty-one received digitalis in some form or other. The maintenance dosage found most useful in the larger group of patients was ½ grain t.i.d.; thirty-two received this amount and the ventricular rate was controlled satisfactorily on this dosage (the powdered leaf) and they were able to pursue their normal activity.

Of particular interest were the eight patients where digitalis was not used. These patients received no digitalis at all, their ventricular rate being satisfactory, and their symptoms being controlled without digitalis. It seemed to be wise not to give digitalis to these patients for the following reasons. One case, because of marked bundle branch block, another paroxysmal case received none, and six patients because their ventricular rates were satisfactory.

Activity. With regard to the activity of these patients, they were cared for as ambulatory patients pursuing their ordinary habits of life, and were encouraged to take a moderate amount of exercise within their

capacity. In a number the fibrillation does not interfere with unusual activity. Golf can be played by some, a number can walk several miles a day without discomfort, one male married at seventy-six years (after fibrillating for eight years), and then lived to be eighty.

With regard to activity, the most important point is the control of the ventricular

Occurrence of Embolism. In the entire series, hemiplegia occurred in six examples, all of which were males (4 hypertensive and 2 nonhypertensive). It is difficult to be certain whether the hemiplegia was embolic or due to a cerebral endarteritis. It is quite probable there were other emboli which missed observation, the brain being the place where the occurrence is least likely to be overlooked.

Taking the hypentension factor into consideration in our observation of these examples, it is our opinion that embolism is rather rare.

Syphilis. The question of syphilis was analyzed. In two nonhypertensive males there was a rather definite history of a syphilitic infection, but only in one, a hypertensive female, was there a positive Wassermann present and there was apparently no etiological relationship between the auricular fibrillation and the specific infection although difficult to prove.

Relation to Bacterial Endocarditis. In our follow-up of this group, no case of auricular fibrillation which we had observed had developed infective endocarditis.

Sudden Death. Although it has been stated that sudden death is not uncommon in auricular fibrillation,10 in our group sudden death occurred only three times, all in nonhypertensive patients, two males and one female.

CASE 1. An obese female, aged fifty years, dropped dead twelve days after examination while going up the elevated railway stairs. She gave a history of attacks of precordial pain for three years previous to examination. Three months before her death, she experienced difficulty in getting her breath without apparent reason, accompanied by radiating pain in chest and left shoulder, especially at night. The patient was taking ½ grain digitalis t.i.d.

Case 2. An obese, alcoholic male, aged fifty-one years, died five months after examination while engaged in public speaking. Digitalis was being used, dosage ½ grain

Case 3. An obese male, aged sixty years, died suddenly three years after examination (on arrival home from a trip) of what was called "acute indigestion." Patient received digitalis grain ½ t.i.d.

Duration and Mortality

An analysis of the duration of life of these patients with arteriosclerotic auricular fibrillation was made on the hypertensive and nonhypertensive groups, and brought out the following facts:

Of the whole group of sixty-nine, there are twenty-seven alive, thirty-four dead and eight with follow-up impossible.

Twelve females lived five to twenty years after the onset of fibrillation (4) still alive); twenty-five males lived five to sixteen years after onset of fibrillation (7 still alive); and more than half of the entire group lived more than five years. The fact was also noted that, for some reason or other, if these patients lived more than five years with auricular fibrillation, they seemed to live a considerable time longer.

Subdividing the series into hypertensive and nonhypertensive patients with reference to duration, it is revealed that in the hypertensive group of twenty-nine there are twelve living, thirteen dead, and four with follow-up impossible, of which nineteen lived five to twenty years and ten lived one to five years. In the nonhypertensive group of forty, there are fifteen alive, twenty-one dead and four impossible to follow up, of which nineteen lived five to eighteen years, and twenty-one lived one to five years.

THE PRACTICAL MANAGEMENT OF DERMATITIS WITH AN ALLERGIC ETIOLOGY

HERBERT H. BAUCKUS, M.D., Buffalo and CARL F. SIEKMANN, M.D., Buffalo

In the field of dermatology diagnosis is in most cases directly definite, and the treatment following usually practical for relief and cure. But the view is often expressed by the general group of the practitioners in medicine that our record in the treatment of the various sensitized inflammations of the skin is rather spotty and unsatisfactory. The public also is imbued with this opinion and is inclined to turn to the allergist for that information and help which properly ought to be given by the allergist to the practicing dermatologist. Continued studies of allergic phenomena are necessary to improve our practical therapeutic methods. As a result of much careful observation by keen workers it appears that we are fairly well agreed how to broadly define allergy, but a practical evaluation of the manifestations of allergic phenomena will require a more clear understanding of the subject.

The cases in our series from which these observations and impressions have been made are those simply in which it appeared that there was some alteration of tissue reaction, allowing a dermatitis to develop. The word "allow" is used advisedly. They include contact dermatitis to the point where we were confused as to whether or not we were dealing with a caustic dermatitis venenata. It appears reasonably enough that allergic phenomena are so common that in many cases they might be considered practically physiological variations. Vaughan1 mentions allergy as a pathologic exaggeration of a normal physiologic response and asks the question, IV hy do not all individuals manifest allergy? It occurs to us that it is quite possible all do. It also appears that the chance and the time for the development of an allergic reaction is dependent on many factors, modified by conditions in some cases well understood, and by some which are not really understood

at all. But it is the patient that has our manifest and most compelling interest,—it is the patient I am especially thinking of in this paper on managing a dermatitis associated with an allergic etiology.

The allergic patient must find it possible to give a careful and thoughtful history. It requires the personal and individual attention of the physician. It requires judicious interrogation by one with clinical experience in the subject. Dermatologists have long expressed their views on the misleading aspects of the history. Here again it is most important not to jump to conclusions. Opinions positively, prematurely, and often erroneously expressed on etiology and prognosis based on the history of the case, often cause an early loss of confidence on the part of the patient. Too often a suggestion causes the patient to color the history. More important than this is to guard against positive statements based on a negative or positive, scratch, intracutaneous or patch test.

An adult female patient presents a spreading dermatitis originating on the face and neck. She has a primrose in her home; her patch test to this is positive; her scratch test to egg is likewise positive; she uses a stimulating hair lotion whose patch test is negative, but the eruption began soon after the patient began to use the scalp application. What caused the trouble? And what do we conclude, when the dermatitis continues to spread in aggravated form for some indefinite time after all the above causes have been withdrawn? Possibly the real cause is orris root, cold cream, white gold, fur, possibly a group food sensitivity. possibly infection, possibly some hereditary and more inaccessible allergic etiology.

In many of our cases we never have determined the real cause of the trouble. Here of course, we need a careful and thorough allergic investigation. But during the acute stages of inflammation this may aggravate the condition. For various reasons the patient wishes to defer the investigation. But she does not want to defer measures for prompt relief of the distressing symptoms. It may be that delay in treatment may convert a minor allergy into a major one. This may also happen from stimulating and irritating treatment. For instance we believe that severe sensitized dermatitis may follow over treatment of scabies.

This patient will do best with rest in bed, at least, with a minimum of physical exercise. This will temporarily eliminate occupation, certain clothing, cosmetic preparations on contacts, influence of sun and wind, heat and cold, outdoor dusts, animals, and some plant pollens from the etiology, and make for a more stable vasomotor function. We can eliminate feather pillows, wood, plants, and dust from the room. The patient may here avoid contact on scalp, face, body with soap and with cosmetics of all kinds. We may eliminate egg, wheat, milk, veal, pork from the diet. We may set up a limited elimination diet of say ten nourishing foods following the elimination methods of Rowe.2 These few foods and their groups may be tested by scratch tests and those found negative tested intra-cutaneously. Positives are eliminated from the diet. If the negatives are false the limited variety of the diet minimizes the chance of error. A recheck may be warranted. We have found variations in a repetition of the scratch test but seldom a marked positive reaction to intracutaneous test following a negative report. We do not feel that a routine complete food sensitization examination is called for at this time in this kind of case. We should investigate the possibility of infection. The procedure is essentially one of elimination. To quiet the vasomotor irritability is of paramount importance. So many cases of acute dermatitis are ambulatory for weeks and months, their inflammations spreading, their suffering becoming more acute, their illness gradually changing into a chronic and serious major dermatitis, when a short period of rest and soothing treatment at the onset would soon result in symptomatic cure. Patients with dermatitis ought to be regarded as sick before they reach the stage of dermatitis exfoliativa. Our experience impresses us with the number of mild cases of allergic

dermatitis of all kinds which are allowed to go to an unwarranted point of severity merely because the physician is looking only at the allergic etiology of his problem. This is unfair to the allergist, to the dermatologist, and most important of all to the patient.

The inflamed skin in our patient is hot, red and engorged. An application of even the blandest oil or ointment will hold in the heat, increase the distressing vasomotor dilatation, and the film of oil will hold in the serous or purulent discharge and prevent drainage from the skin. A cool continuous wet dressing properly applied will relieve most quickly and also has the best curative action. We prefer to use half saturated boric acid solution. An astringent lotion may act well but it should not contain any antipruritic agent, or it may cause a burning sensation. There may be an allergic response to this. A negative patch test of a therapeutic application may be helpful but the normal skin may not react where the inflamed skin will. A lotion of twenty per cent bismuth subcarbonate in water is mildly astringent, soothing, and in our experience safer than that of zinc oxide. In reactions associated with urticaria, calcium internally may be of value. Some cases will benefit from regular colonic irrigations even where the prime etiology was not internal. This procedure sometimes is of value in chronic cases. With the above practical and simple measures augmented by attention to specific demands and details most patients will make a symptomatic recovery. Confidence will be established so that a more exhaustive and efficient research may be made.

When the patient cannot or will not remain indoors the same methods of elimination ought to be carried out as far as possible. If the disorder is occupational a temporary vacation or a change in the character of work is indicated. There are cases in which the sufferer cannot remain in the building, especially a factory, in which the allergic dermatitis developed. Do not advise a person to give up a life's vocation at the first visit. He will first give up his physician. Our analysis impresses us with the number of cases of occupational dermatitis, which have become susceptible to an allergic contact dermatitis because of a departure

from normal of the skin structure. The worker with the dry skin, with fissuring and so called chapping, with sweat gland disturbance, with certain illnesses including endocrine disturbance is the most susceptible The climate, especially cold, may have an influence A man at work comes in contact with the same chemicals for years without trouble. The day comes when he washes his hands with a highly caustic soap From then on he develops an occupational dermatitis even though he never uses the soap again Improperly drying the hands after washing may lead to a fissuring dermatitis. Much may be done to prevent occupational contact dermatitis, especially a localized allergy, based on the fact that the normal skin is the least apt to develop trouble. Such a simple thing as the use of a cake of cocoa butter on the hands a few times daily may restore the dry fissured irritable skin to normal, and prevent more trouble The worker must not be care less and unclean

With care and patience many of the acute cases of allergic derinatrits will have their etiology discovered Some will get well and stry well on symptomatic treatment alone even though we do not make an etiologic diagnosis Because of our inadequateness, sometimes because of lack of cooperation on the part of the patient, and often from various other causes, it is our experience that many of the acute cases become chronic A few points may help to take care of this situation

The frankly allergic such as the eczematous asthmatics often have a dry skin Attention to this does much for the patient even where the allergy and the asthma continue to be outspoken. It takes a great deal of oil applied for months to soften this kind of skin Oil to the skin on going to bed warms the skin and causes intolerable itching, therefore oily preparations should be used during the day and a simple powdery lotion at night There is no doubt that some cases of this kind respond to thyroid More endocrine knowledge may help in this problem 3 The asthmatic eczema case may be helped a great deal by proper care of the skin He is entitled to more thought than that on allergy alone

Patients with areas of indurated skin as

in neurodermite will have relief from x ray. The benchcial effects of this in long standing cases may cause the patient to seek so much x-ray that finally atrophic disturbances arise. It is interesting to note how well crude coal tar acts in most cases of chronic dermatitis. We use a crude coal tar obtained from the gas works and it is made to consist of sixty per cent distillate and forty per cent pitch Every effort should be made to have a nonneritating tar Still more important is it to have the tar incorporated in a nongreasy or vanishing cream base. It is much more effective and much less irritating, it might even be said that this base is essential. The preparation is gently and thoroughly applied once a day, and immediately and gently wiped off It is a mistake to cover the skin with a large amount of omtment and allow it to remain on, or even worse, bandage it on This principle applies with equal force to any cerematous inflammation some cases of induration that will respond best to this type of medication if an application of boile acid wet diessing immediately precedes for one hour. This softens and drains the skin, and allows the crude coal tar to be twice as effective Nothing acts as well as this combination This is also true in the treatment of obstinate deep epidermophytosis, where the crude coal tar alone may prove in**efficient**

At this point it should be said that it appears to the authors that the diagnosis of the tricophyton organism causing an acute or a chronic allergic dermatitis is too often erroneously made The ringworm lesions of the toes and soles continue merrily with us, but a study of our cases tends to show that some, not all, of the cases of dermatitis of the hands classified as epidermophytid are really occupational contact dermatitis associated with sweat gland abnormality. The same point may be made in the so called secondary ringworm infection often supposed to complicate dermatitis venenata Possibly it is one of the reasons for partial failure of tricophytin extracts in diagnosis and treatment. The subject might well take an entire paper. It is merely recorded here as an observation

The role of infections in allergic dermatitis is undoubtedly important. We

must try to eliminate all foci. But again it is easy to arrive at an erroneous conclusion. Let us consider the following illustrative case:

Patient has the tonsils removed. The protein reaction from the blood clot, the protein reaction from the liberation of bacteria into the blood stream, the rest in bed, the change of environment, all may serve to bring about the picture of an apparent cure. But too often the symptoms and signs return and another physician takes up the investigation.

Acute and chronic inflammations of the skin produce changes in skin pathology. These persist even when the allergic factor has been discovered and removed. Intelligent treatment of the skin must now follow. The diagnosis of the skin pathology must be correct, as more than one disease of the skin may be present. The location of the allergic dermatitis demands our consideration. The complications of seborrhea of the scalp, secondary pustules in hairy regions, complicating impetiginous inflammations of the face, a combination of impetiginious, seborrheic and intertriginous factors about the ears, infection and intertrigo under the breasts, in the axillae and groin, and congestive influences in the lower extremities, are only a few of the many factors with which we must contend in our therapeusis. Our experience in the use of maize and linseed oils in certain deficiencies is limited, but has not yet been found very favorable. Hereditary influences are interesting and in many cases undeniable.

Special reference should be made to allergic dermatitis in infants and children. It is well at first to consider most all cases allergic in etiology, but we find that there often is an initiating or incentive stimulus. The baby with a simple seborrhea of the scalp or with a vesicular sweat gland dermatitis may be treated in this stage and the skin manifestations of its allergy prevented. Sometimes oily and stimulating applications to this vesicular dermatitis pushes the process over into a frank allergic inflammation. In our analysis of infantile eczema, we found thirteen per cent with a seborrhea of the scalp and twenty-five per cent with symptoms of sudaminal dermatitis. The use of soaps and water, oils, especially

those designed to disinfect the skin, contact with woolen and silk clothing, too much clothing, too warm rooms, exposure to heating sunlight, wind and cold, effect of decomposing urine, insufficiently rinsed diapers, chemically treated toilet seats, scratching, irritants to the young tender skin ad lib all contribute to make a venenating dermatitis develop into an allergic symptomatic chronic process. A soothing powdery lotion applied several times day and night to constantly cover the skin finds an invaluable place in our therapeutics. A good five per cent crude coal tar salve, in a nongreasy base, during the day (never at night), and wiped off immediately after application almost invariably is beneficial. The treatment of infantile eczema is of course a broad problem, but early and preventative care of the allergic makes it a much more satisfactory one. Of course the diet is important. Egg and wheat should be eliminated at once until thorough investigation may be made.

In general, efforts at direct sensitization, especially inoculative procedures produced poor results. It was felt that more was being accomplished by taking care of the skin in such a manner as to minimize inflammation and local reaction and by the elimination as far as possible of the etiologic allergy. A few patients with occupational dermatitis under certain restrictions were able to recover and remain at their same occupation. In some a change of occupation was necessary. It is quite well-recognized that with time and favorable influences, many cases of skin allergy lose their sensitivity. This is an important thought in taking care of all these cases.

Conclusions

We wish to express our appreciation of the material, and references on allergy and immunology presented in the 1934 year book of Wise and Sulzberger. Our clinical observations may be briefly summarized as follows:

1. Allergic dermatitis is common and quite likely some sensitization symptoms may be awakened in any person.

2. The allergic reaction may be dependent upon a combination of causative allergic influences.

3. A combination of one or more

allergic factors with one or more nonallergic circumstances accounts for most cases of allergic dermatitis.

 Some cases of allergic dermatitis, including occupational dermatitis and infantile eczema may be prevented, and many cases minimized.

5. The normal skin is less apt to develop inflammatory manifestations of

allergic sensitization.

- 6. Symptomatic treatment is important in preventing the development of a major allergic dermatitis from a minor one.
 - 7. The pathology of the skin lesions

remaining after the allergic cause has been removed requires therapeutic attention.

8. The patient suffering from a dermatitis with an allergic etiology requires symptomatic treatment before, during, and after the removal of the allergic cause. 925 DELAWARE AVENUE

Discussion

Dr. Leon H. Griggs, Syracuse-I have enjoyed Doctor Bauckus' paper and admire his courage in preparing such a paper on this very complex problem that confronts us at all times in the practice of dermatology.

The term, allergy, can be defined simply as "altered cell reactivity" but it has a more profound meaning in its relation to diseases of the skin. Physicians at large have become more allergy conscious and without doubt, many physical ailments have been improperly placed in that class. Many practitioners have classed themselves as allergists and I believe that many of them are too enthusiastic as to their end results. As a result, the laity has become quite allergy conscious and many are anxious to undergo the various skin tests with the idea that a "serum" can be given to relieve their condition. I do not mean to belittle the efforts of the allergist but I do believe that we must maintain a more conservative attitude.

I agree with Doctor Bauckus that an exacting history is of prime importance in the early management of a case of allergic dermatitis. I believe that it is of most value in the determination of the prognosis of the case.

I feel that the next step is to attempt to determine, if possible, if the skin condition is a true allergic manifestation. The esuption may be a simple local sensitization or contact dermatitis. In this latter type, I am sure that the outcome will be much more satisfactory. Doctor Bauckus has shown the various methods of this investigation.

It is unfortunate that we do not have a more specific treatment. Many patients have experienced a wide variety of local applications, diets, and physical measures includ-ing x-ray. The allergic patient usually has a vasomotor instability plus an acquired hopeless mental attitude. The treatment of the latter belongs in the field of psychotherapy. It has been my observation that a true allergic patient will show temporary improvement whenever he changes physicians. I believe that with the chronic patient, one should instill a reasonable amount of hope.

I am pleased to note that Doctor Bauckus spoke of the value of horic acid compresses. It has been my experience that there is a tendency to overtreat this type of case. There is no doubt as to the value of crude coal tar but it must be applied only after the acute inflammation has subsided. X-ray therapy must be used in a conservative manner as it appears in most cases to be

only a temporary relief.

I believe that the presence of foci of infection and other factors as a seborrhea have an influence in lessening the normal resistance of the skin and the individual.

In conclusion, I can only add to Doctor Bauckus' remarks that the treatment of an allergic dermatitis must include a great amount of thorough investigation and thought.

Discussion

Dr. Samuel M. Peck, New York City-In the past it has been necessary to do a large number of routine patch, scratch, and intradermal tests in cases of eczema in infants and children. This phase of the attack of this very complex disease had to be gone through because of the lack of statistical data. A number of workers have published

their results in this group of cases, and I have come to the conclusion, based both on their work and my own, that while skin tests are often of value, certainly the num-ber of tests to which a patient must be submitted is a very limited one. As a matter of fact, it is more important to eliminate from the patient's environment, contact

factors, and from the diet, those substances which by tests and clinical experience have proven to be frequent etiologic agents for the allergic manifestations. Only then, should a very limited number of tests be done. Certainly, any sort of a routine examination comprising a very large series of tests of any character is to be avoided. It is very important to emphasize that in the last analysis, the most important therapeutic measure consists in topical applications of

one sort or another in the great majority of cases. The dermatologist, because of his knowledge of differential diagnosis of skin diseases, and because of his long experience in the treatment of such cases, is surely the one to treat these cases. In the main, it is the consensus of opinion that the promise held forth by the skin tests in bringing about the cure of eczemas in infants and children, has not been sustained in a very great many cases.

THE DOCTOR'S WIFE AND "MRS. BROWN"

The botheration caused by the various "Mrs. Browns" in the doctor's practice is treated with good humor and good sense by a doctor's widow. Mrs. Amy Jones, of Omaha, in The Medical World.

You may have planned a foursome at bridge, she says, a dinner party or a night out at the club; but if Mrs. Brown "has one of her spells" your partner must leave the festivities and perhaps spend the most of the evening with "Mrs. Brown" and other patients who may call before he returns, and need immediate attention. You may want to bang up the 'phone and scream, but instead you must always play the part of the gracious doctor's wife who takes the message that sends your husband out on another trip when you are lonesome for his company. Remember to repeat the number and address; also be careful to get the name correctly. This is of vital importance. It may mean life or death in case the message is not taken correctly.

Frequently your husband will spend most of the night on a confinement case or in an emergency operation. He will be tired and irritable the next day. He must show his best side to his patients, and will not want to be bothered by gossip or small talk at home. Neither will he want to hear your

petty household troubles.

Never allow yourself a thought of jealousy. Always assume that his interest in his patients is strictly professional, even though you may stop in at the office and find the same charming woman just emerging from behind closed doors time after time. In no few cases in the smaller cities the "charming woman" may be your old rival. Your heart may ache and you may see "red," but you must remember his professional obligation, even though you may want to ask him the nature of her ills. You must always bury the "green-eyed monster" along with the many, many disappointments that will come your way. Your doctor's success depends upon the service he is able to render the suffering public, and your part

in that success depends upon keeping his home a haven of rest and contentment, and meeting all situations with fairness and poise. I often think of the old shop-worn aphorism; "Behind every great man is a greater woman." This holds true in the medical profession more than in any other line of endeavor. A successful doctor's wife must be loyal, loving, sympathetic, kind, broad-minded, good-hearted, conscientious, honest, and, above all, a good sport about everything. In spite of all the sacrifices, should I ever remarry, my choice would be a doctor.

Alumni Day of the New York University College of Medicine will be held on Saturday, Feb. 22, at the medical college. The program which extends through the entire day includes the presentation of medical papers, laboratory demonstrations, exhibits, and rounds in the wards of Bellevue Hospital. Luncheon will be served in the Students' Lounge in the old building, 26th St. and First Avenue, and the annual dinner will be held at the Park Central Hotel.

MEDICAL RADIO BROADCAST

The Medical Information Bureau of the New York Academy of Medicine announces the following broadcasts from Station WABC and the Columbia Broadcasting System network:

Thursday, February 6, 1:45 P.M.— Speaker: Dr. Anthony Bassler, Consulting Physician of St. Vincent's Hospital, New York City. Subject: "The Human Body, The Power Plant and Its Fuel."

Lady: "What makes you so late with the milk these mornings?"

Farmer: "Well, you see, the pure food law only allows us to have 25 million bacteria to the gallon and you'd be surprised how long it takes to count the little rascals."—Food Facts.

A STUDY OF INFANT CARE IN A RURAL COMMUNITY

MARJORIE F MURRAY, M D, AND RUTH I LYMAN, M D, Cooperstown

In any attempt to improve the health of a community, it is obvious that one of the major considerations should be that of raising the standards of infant High infant mortality and morbidity rates have long been recognized as a sign of poor health standards, while a dropping infant mortality rate is often used as an index of general improvement of public health. With increasing interest in preventive medicine much has been done during the last twenty-five years in the field of infant care Improved obstetrical methods, campaigns to eradicate diphtheria, control of milk supplies with compulsory pastcurization of milk, and many other factors, have all contributed to a world-wide lowering of infant mortality

In the United States the rate for the total registration area in 1915 was 100 infant deaths for every 1000 live births in upstate New York, 101 By 1924, upstate New York had brought its rate down to seventy-one and this figure dropped fairly steadily until in 1934 it reached fifty two, the lowest figure in the last ten years. It has been well proved that this lowering of the death rate of infants is not a mere saving of the unfit, but has been a part of a general improvement in the health of children

Of the various factors contributing to this improvement of infant health maternal education is one of the most important. In most of our urban communities today, infant feeding stations and well baby chines are serving a large group of individuals, and have un doubtedly done much to raise the level of health in the young children of these communities They are sponsored by hos pitals, visiting nurse associations, and various other public and private agencies In our rural districts, however, there has been much less concerted effort in paren tal education and infant supervision. In New York State, baby clinics are held in rural districts under the auspices of the State Health Department but such clinics are held infrequently in any one community, and there is little opportunity of following the individual child through them Public health nursing service is limited in its function in the rural areas because of the distances that must be covered and the time consumed in attempting to visit individual farm homes. The dissemination of information by such means as are found of value in the cities (i.e., by lectures, exhibits, posters, etc.) is impractical for the same reason. The very groups who most need help, are too remote and scattered to be reached.

Morcover, the rural population is fundimentally conservative. Habits and customs are deep-rooted and hard to change There is a vast amount of folk-lore and tradition concerning the infant which is handed down from one generation to another, and grandmothers and greatgrandmothers exert a widespread influence It is just as hard to convert the farmer's wife to modern methods of child care as it is to persuade the farmer to use modern agricultural methods, although no group of fathers is more intelligent and cooperative in the matter of bringing up children than the enlightened farmers who can see the obvious parallel between their problems of husbandry and the problems of child

In this matter of educating parents to give their babies better care, the most important person in the community is usually the family physician This is much more true in the country than it is in the city where pediatricians are easily available and special baby clinics for both well and sick children are usually offered to those who cannot afford the services of a private physician. It probably takes special training and some peculiar turn of mind to find the problems of the infant, its feeding, its daily routine and its habit training of absorbing interest It certainly is not a field enjoyed by most physicians whose work is largely with adults and only incidentally with children, and for this reason it is frequently neglected The family physician who gives excellent care to the sick infant, is often uncertain in his approach to nutritional problems. We have all seen infants put on feedings obviously deficient

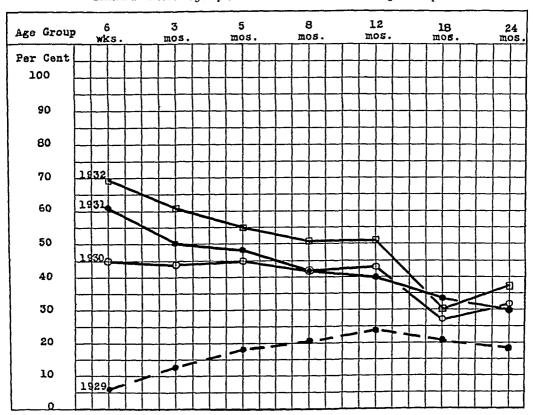

in caloric, protein, or vitamin content, and changed from one sugar to another or from one proprietary food to another, in a vain attempt to solve a relatively simple feeding problem. Few physicians received much training in their medical school days as to the details of an infant's daily life and the matter of habits and habit problems, and it is only through individual interest and study of this phase of child care, that a fund of knowledge and experience is accumulated that can be passed on to the mother. The average general practitioner has no especial interest in these problems.

That most precarious period in the infant's life, the first month, presents peculiar difficulties. The care of the baby for the first few weeks is usually in the hands of the obstetrician, whose fundamental interest is in the mother rather than in the offspring. However much attention he gives to the child, he seldom pretends to be a specialist either in infant feeding or in the diseases peculiar to infancy. The transition between the care of the obstetrician and that of the

pediatrician or family physician, is difficult for the mother whose habit it is to call a doctor only for a case of illness. Often the baby drifts along after the obstetrical period with no supervision until some definite signs of sickness appear and unsurmountable damage has been done.

With these facts in mind, a cooperative plan was drawn up in July 1928 at the Mary Imogene Bassett Hospital in Cooperstown, between the departments of obstetrics and pediatrics. The infants born on the obstetrical service, were placed under the care of the pediatric service from birth. This method had been used in a number of large city hospitals and had proved successful. In our experience at Cooperstown in the last seven years, there has been no difficulty, but rather an increasing sense of cooperation and mutual helpfulness between the two departments. Our maternity service cares for about one hundred in-patients a year. It is a small, self-contained unit in a general hospital of about seventy-five beds. There are certain advantages in the very

CHART I-Percentage of Clinic Attendance Shown in Age Groups

smallness of the service. It is possible to care for the patients under relatively stable conditions. The direction of the services is not passed from one attending to another, but has remained under the same guidance. A pediatric intern cares for both the infants in the nursery and the medical cases in the children's nard. The nursing staff is made up of graduate nurses, and is infrequently changed. A nurse with pediatric training is usually in charge of the nursery. Every effort is made to maintain a high standard of nursing technic, and the babies are cared for on the individual isolation plan with the attendants using mask and gown.

The community served is definitely rural. Cooperstown itself has a population of about 2700, and is surrounded by a farm district with scattered hamlets and villages. The maternity patients represent an economic group probably a little above a true cross-section of the community, although a good many of our very poor come to the hospital and there are very few that could be classed as rich. It is doubtful if more than a dozen babies born in the hospital, in the last seven years, have had nurses to care for them at home.

One of the aims of the pediatric de-

partment in taking over the care of the obstetrical babies, was frankly educational. To interview the mother during her hospital stay, start her on a sound regimen and teach her how to handle her baby when she returned to her home, was one part of the plan. The other part of our program was supervisory as well as educational, and consisted of a series of follow-up clinics offered without additional charge to the mothers of all babies born in the hospital. The mother is notified by card at definite intervals (i.e., when the baby is six weeks, three months, five months, eight months, twelve

in the pediatric offices at the hospital.

Clinics were practically unknown to the community at the time that this service was started. The mothers were hesitant and doubtful. They were frankly skeptical of the kind of care the babies would

months, eighteen months, and two years

old) and asked to bring her baby to the

clinic. She is given a choice of two clinic dates, the clinics being held once a week receive. As a result, our early attendance was discouraging. Our program was in full operation by January 1929, and yet, of the eighty-five babies born in the hospital in 1929, only six returned at six weeks, eleven at three months, and fit teen at five months. (Chart I.) By the time these babies were eight months to

a year old, the attitude towards the clinics had begun to show a change, and the numbers returning for supervision were increasing and a steady improvement in attendance has been observed since then. Thus, of the babies born in 1932, sixtyseven per cent returned for examination at six weeks, nearly as many at three months, and about fifty per cent at the ages of five, eight, and twelve months. The poorest attendance (30 per cent) was at eighteen months, but at two years it had increased to thirty-seven per cent. In the five years under consideration, the total number of infants making use of the clinics has shown a steady increase from fifty-nine per cent in 1929 to eighty-eight per cent in 1933, with an

III, the attendance record of the infants who came from the more distant homes compares very favorably with those from homes in the immediate vicinity of the hospital. Distance seems to have offered no serious obstacle to the mothers who felt the need of the service offered, and even during the winter months when the roads are often covered with snow and ice, there has been remarkably little drop in the clinic attendance.

In such a service as we offered, we hoped especially to reach those mothers and infants whose need for it was greatest, i.e., the very young mothers, the mothers of first babies, and that group economically unable to pay for such supervision. Of 427 babies born in the

CHART V-Weights of 167 Infants Under Adequate* Clinic Supervision

average of seventy-six per cent for the whole period. (Chart II.) Since fifty-five per cent of our maternity patients live more than ten miles, and fifteen per cent more than twenty miles from the hospital, we had hardly hoped that so many of them would return to the clinics. As a matter of fact, as is shown in Chart

hospital between January 1929 and July 1933, sixty-eight were the children of mothers under twenty-one years of age and 189 were first babies; and as is shown in Chart IV, the best records of attendance were made by this group. Of these first babies, eighty-three per cent were brought back to clinics; of second babies,

766 per cent, while among the babics from larger families there was a gradual falling off in attendance

Concerning the economic status of our patients, it is more difficult to accumulate data. In an attempt to classify them from this standpoint, we found about forty-six per cent of them belonging to the poor or border line groups, forty eight per cent to the economically stable group of salaried workers, farmers, etc., and only six per cent from really well to-do families. Relatively few of this upper stratum made use of the clinics, since some were summer residents returning to their own physicans in other towns, and some were supervised as private patients. Of the large group in what might be considered comfortable cir-

cumstances, many came from families with good living standards but with low incomes, people who would find it difficult if not impossible, to pay for such supervision as they received. Thus we felt consinced that most of our work was with those who needed the service and who would not otherwise have received regular medical supervision.

As is true with any attempt to influence something as intangible as general health standards, it has been difficult to evaluate the results achieved by our chine program. Have these chines really raised the level of health of the community, and given us a group of children who would have been less well off without them? To those of us who have spent our energies in some

1600 interviews with mothers and examinations of infants, the answer to this question is of vital importance. To measure results, we must briefly review the work done.

Our general plan has been as follows. At each clinic, every infant is thoroughly examined and the mother is questioned about the general health of the baby, about his habits (bowel, feeding, sleep, etc.) and about any illness or gastrointestinal disturbance he may have suffered. Written records of the history and physical findings, and of the advice given, are kept.

Each infant presents his individual problems, but most of our babies have been cared for on the same general regimen. Breast feeding is urged, but is frequently supplemented. Cod liver oil is started before the infant leaves the hospital, orange juice or tomato juice at six weeks, and solids at the fourth to fifth month. A four-hour schedule is the general rule. Some infants are on four feedings daily by the third month, most by the fifth month. The formula most commonly used is a simple and inexpensive one—two parts whole milk, one part water. and eight per cent Karo syrup, cooked for fifteen to twenty minutes in a double The mothers are taught how to increase this formula with gradual concentration, until cooked whole milk has usually replaced the formula by the eighth month. At this time, most infants are on a three-meal-a-day schedule with one extra cup or bottle of milk. Advice concerning fresh air, sun baths, appropriate clothing and shoes is given, and the mother is taught how to protect the baby from infection. A very definite effort is made to reduce the work involved in caring for a baby. Most of our mothers do their own housework and care for their children unaided, and we try as far as is possible to simplify the babies' schedules. Although we insist on regularity of hours, we stress the fact that a baby does not

need to upset a whole household nor seriously interfere with the mother's duties to the rest of her family.

As to results, from the standpoint of general impressions, they have been gratifying. Most of our babies are easy to care for, and grow and develop in a satisfactory manner. One is likely, however, to unconsciously remember the encouraging and forget the discouraging case, and for this reason we have attempted to evalute our results more accurately; first. by analyzing in detail the records of a group of babies that we felt had received adequate clinic supervision; second, by comparing our infant mortality statistics with those of Otsego County as a whole, the district from which most of our patients come. We considered adequately supervised, those babies seen at least three times; the first visit during the first five months and the last at twelve months, eighteen months or two years. These requirements were met by 167 infants, with an average of 5.2 clinic visits each.

In this group of adequately supervised babies, the general condition of each child at the last examination was graded as Excellent, Good, Fair, or Poor. As Excellent, were classed those with no physical defects except perhaps slightly pronated feet, a finding so common that it might well be considered normal in the child who is begining to walk. As Good, were classed those with one or two minor defects such as slightly flaring ribs, mild eczema, or red tonsils, but whose nutrition and development were normal. Fair, were classed those with several minor defects or those who seemed somewhat below par in nutrition, color, muscle tone, or general appearance (some of this group had recently recovered from a severe illness at the time the examination was made). As Poor, were classed those whose health and physical development were definitely defective.

By this grading, 46.5 per cent were in

CHART VII—Comparative Mortality Statistics, Otsego County, Bassett Hospital (1929—33)

Excellent condition, forty-two per cent in Good condition, 11.5 in Fair condition, and none in Poor condition. Such estimates are obviously inadequate, but were made with every effort to form an unbiased opinion from the facts presented

in the records.

The weight distribution, at the ages under consideration, bear out the general impression. (Chart V.) The average weight of the twenty-seven infants last seen at one year, was twenty-one pounds and six ounces, of the ninety-two infants last seen at eighteen months, twenty-six pounds and nine ounces, and of the ninetytwo infants last seen at twenty-four months, twenty-nine pounds-figures a little higher than those for the corresponding ages usually accepted as normal. There was as seen in the chart, a wide spread between the high and low weight figures in our groups, but we were impressed with the fact that this variation was more often dependent on type than on state of health. The small-boned, delicately-built child weighed much less than the large, heavilybuilt child of the same age, irrespective of general condition.

Practically all these children were found to have received cod liver oil and orange juice regularly throughout infancy. For three months or more, 102 (or 61%) were entirely or partially breast-fed. Almost all of them were receiving solids by the fifth month, and were on a general diet by eight months to one year, The morbidity records of this group of infants have been analyzed in some detail and are shown in Chart VI. We found no cases of serious nutritional disturbance in the group. In spite of early and faithful administration of cod liver oil, however, twenty-two babies were noted as showing some signs of rickets of a questionable or mild type. The diagnosis in these cases was not based on x-ray findings, but on the presence of some flabbiness of musculature, flaring ribs, or other clinical evi-dence of rickets. In the very mild or questionable cases, such findings were usually observed at one examination only. Serious gastrointestinal disturbances were rare. If the two cases of bacillary dysentery he excluded, there were only three

cases of serious diarrhea. Of the 167 infants studied, there were ninety with no gastrointestinal disturb-

ance of any kind, 128 with none other than mild constipation, and only five with serious gastrointestinal disease. It is surprising to find almost as many serious surgical conditions in this group of infants as there are serious nonsurgical gastrointestinal diseases. Respiratory diseases were common; ninety-nine infants suffered from some form of respiratory tract infection, while sixty-nine had never had a cold, or at least none reported by the mother. There were twenty-one cases of serious illness in this group of respiratory Although there were tract diseases. twenty-two cases of contagious disease, most of them were mild and uncomplicated. There were two cases of congenital lues, both of which under treatment became Wassermann negative. Allergic manifestations were fairly common with, however, only three cases of severe eczema or asthma. Of the conditions classed as miscellaneous, pyelitis was the most common. It is noteworthy that only one infant had convulsions.

The conditions listed under illnesses were not all of a serious nature. Of the sixty-nine recorded, forty-one cases occurring in thirty-nine infants were noted as Thus, twenty-three per cent of the babies under observation had some serious illness during the first two years of life. On the other hand, twenty-six per cent had never had any illness more serious than a cold, and thirty-two per cent had had no recorded illness whatsoever. No deaths occurred in this group of 167 infants.

As far as known, morbidity statistics in infants cared for at home are not available, so that it has been impossible

to compare these records with those of others. There is no reason to assume that these babies had fewer illnesses than the average group, but it is obvious that they were strikingly free from nutritional disease and from serious gastrointestinal disturbances. It is also noteworthy that although twenty-three per cent of them had experienced serious illness during the first two years of life, none were in poor condition and only 11.5 per cent were rated as Fair at the end of the observation period. It is perhaps reasonable to believe that this low incidence of digestive disturbance and nutritional disease, and the general good condition of the group, may reflect the influence of our educational and supervisory program.

In analyzing our mortality rates, we have considered the total number of 489 babies born at the M.I.B.H. between January 1929 and January 1934. In order that our figures might be compared with the infant mortality figures for Otsego County as a whole, we have recorded only deaths during the first year of life. There were nineteen deaths among these babies, or a total infant mortality rate of 38.9 per 1000 live births as compared with a rate of 60.9 in the whole county for the same period. (Chart VII.) About one-seventh of the babies born in the county are born at our hospital. Oneninth of the deaths under one month occurred in our group, whereas only onenineteenth of the deaths between one month and one year occurred in this group. The causes of the nineteen deaths in our series are tabulated. (Chart VIII.) Of the fifteen neonatal deaths, seven were due to prematurity and three to birth

injury. Only four deaths occurred in babies who survived the first month, and of these one alone was due to infection, a sporadic and rapidly fatal case of meningococcus meningitis.

In dealing with problems involving infant mortality figures, we realize that our numbers are small and that our low incidence of deaths from such common causes as gastrointestinal disease and pneumonia may be due to good luck rather than to good management. However, it cannot be without significance that in Otsego County as a whole, under the same general conditions and during the same period, there occurred fifty-four infant deaths from infectious disease, respiratory disease, and gastrointestinal disease

In conclusion, an educational and supervisory clinic plan for the care of infants has been tried in a rural community. This plan has proved practicable and of value. The service has reached predominately those who, either because of inexperience or because of economic circumstances, especialy needed it. In spite of the obstacle of distance, there has been a steadily increasing use of the clinics. Over the course of seven years there has been an entire change in the attitude of the mothers to whom the service is offered. Once doubtful of its value, they are now enthusiastic in its support. It is believed that the influence of such education and supervision is reflected in the low incidence of nutritional and digestive disturbances among the babies supervised, and in the low mortality rates from respiratory, contagious, and gastrointestinal diseases.

OSTEOPATHS LICENSED TO PRACTICE MEDICINE IN NEW JERSEY

In accordance with an agreement between the officers of The Medical Society of New Jersey and those of the Osteopathic Society, made in the early part of the year 1935, the two organizations joined in supporting an amendment to the Medical Practice Act defining the conditions under which osteopaths would be given the right to practice medicine and surgery. This Bill was passed by the Legislature and was approved by the Governor on May 23, 1935.

The amended law provides the means by which a graduate of an approved osteopathic school or college may be licensed to practice medicine and surgery, the conditions being that he shall conform to the standards of those practicing medicine and surgery; and that the osteopathic schools and hospitals shall be of a scientific grade equal to those of regular physicians.

In this country the matter of consent to an operation often comes up to plague the surgeon. In England, so we are told, the patient on entering a hospital signs a paper giving the surgeon full freedom to do anything he thinks best for the patient.

PELVIC INFECTION

Laboratory Aids in Diagnosis and Treatment

THOMAS C PEIGHTAL, M D, New York City

Since the epochal teaching of Simpson in 1909 that pelvic inflammatory disease was not an acute surgical problem calling for immediate operative interference, the trend of treatment of these infections has become yearly more and more conserva tive, until, today, probably less than thirty per cent of all types of tubal infection ever come to operation on the average gynecological service. With the adoption of such conservatism in handling this great group of acute cases has developed the necessity of making an accurate differential diagnosis between inflammations of the pelvic structures amenable to expectant treatment and those other surgical emergencies (acute appendicitis, ectopic pregnancy, twisted ovarian cyst, etc.) which call for immediate operative interference In attacking this problem the benefits of a careful history and an exhaustive physical examination must never be overlooked, but even the keenest diag nostician of physical findings usually welcomes the valuable information obtained from certain laboratory data. An attempt to evaluate three such laboratory aids the sedimentation test, the gonococcus complement fixation test and the Frei test will be the aim of this article

The Sedimentation Test

The sedimentation test consists in ac curately measuring the varying speed with which the erythrocytes settle in the plasma of the blood when it has been rendered noncoagulable. The phenomenon of sedimentation was noted as early as the time of Galen, but to John Hunter in 1797 is given the credit of first noting that the speed of sedimentation of the erythrocytes was increased in individuals suffering from inflammatory lesions, and that this speed varied with the severity of the infection From this time until 1850 a number of writers (Nasse, 1836, Davy, 1839, Muller, 1844, and others) recorded their observations regarding this behavior of the red blood cells and sought a satis

factory explanation of it For many years these observations remained buried in the literature until the interest of the medical profession was renewed by the report of Tahracus' in 1917 of his findings of rapid sedimentation of the red cells in the citrated blood of pregnant women 1920 Linzenmeier2 worked out a technic for the test which has been widely used subsequently, and found that even more rapid rates obtained in patients with in fections and particularly those suffering from pyosalpinx From this point on in this country Friedlander³ (1924), Polak⁴ (1926), Baer and Reis⁵ (1926) and many others have demonstrated the great value of this test in obstetrics and gynecology, while more recently Grodinsky (1932), Lesser and Goldberger (1935), and Smith⁸ (1935) have detailed its advantages in general surgery Gruenfeldo (1928), Cutler10 (1932), Bach and Hill11 (1932), Bannick12 (1933) and others have noted its significance in medical cases, particularly rheumatic fever and tuberculosis

Etiology The etiology of the phenome non of sedimentation of the red cells in the plasma has received the attention of many investigators, both here and abroad Some feel it is due to a variation in the constitutents of the plasma while others feel it has to do with the electric charge of the erythrocytes themselves. This lat ter theory is probably the most widely accepted Huber has shown that the red blood cells carry a negative charge and that in normal blood they remain sepa rated by uniform distances since similar charges repel each other In diseased states the red cells tend to lose this electric charge and therefore clump and settle more rapidly in their plasma. The erythrocytes of normal blood, if transferred to the plasma of blood under inflammatory conditions, settle more quickly than in their own plasma

Therefore it is assumed that the bodies which cause the red cells to lose their

electric charge are to be found in the altered plasma. Whether this is due to the changed agglutinins, gobulins or changed viscosity of the plasma is still a matter for debate.

Technic. Most laboratories use one of two technics for the sedimentation test, which differ little as to the method of obtaining the citrated blood, but vary chiefly as to the type of tube in which the cells are placed to sediment.

In the literature most authors have employed the Linzenmeier test as modified by Friedlander. Here the sedimentation tubes are 6.5 cm. in length and five mm. in diameter, with a capacity of slightly over one c.c. They are marked at the one c.c. level and below this at levels of six mm., twelve mm., and twenty-four mm. The sedimentation time is the number of minutes it takes the red blood cell column to settle to the eighteen mm. mark. Eight-tenths cubic centimeter of blood is drawn from a vein with a syringe containing 0.2 c.c. of a freshly prepared five per cent solution of sodium citrate.

Although Friedlander found the normal sedimentation time in healthy individuals to be 1000 to 1200 minutes in males and 600 to 1000 minutes in females, readings are not usually considered abnormal unless they are less than 120 minutes.

The Westergren¹³ technic is the other frequently used. In this 0.4 c.c. of 3.8 per cent of sodium citrate solution is placed in a syringe into which is drawn blood up to two c.c. This is thoroughly mixed in a test tube and the citrated blood drawn up in a pipet two mm. in diameter until a column 200 mm. in height is obtained. This pipet is calibrated downward from the 200 mm, mark in millimeters and the test is read noting how many millimeters the column of red cells settles in an hour. Normal healthy blood settles three to fifteen mm. in an hour. Some feel that the capillary attraction and friction of cells in this narrow pipet makes this method less accurate, but the error is insignificant. The writer prefers the Westergren technic because of the practical advantage that the test only requires an hour and one reading at this time suffices.

Others use the Weiss¹⁴ technic in which the citrated blood is placed in a special two c.c. cylinder which is graduated from one to one hundred so that readings are made in percentage of the fluid column. Readings are made every fifteen minutes for one hour and normal is between three and five per cent in forty-five minutes.

Results. Since 1930 all admissions to the gynecological service of the Roosevelt Hospital, from which this report is made, have had the sedimentation test. It is on the basis of this experience in coordinating this test with the leukcocyte count, temperature, and other clinical data that the following observations are made in regard to diagnosis, prognosis, and therapy in pelvic infections. The Westergren technic has been used and readings recorded in millimeters of sedimentation at the end of one hour.

It must be emphasized that this test is not a specific diagnostic sign for any disease, but that it does indicate the presence or absence of an inflammatory process somewhere in the body, and in some inflammatory conditions it may be used in part to estimate the severity of the infection. Thus it becomes evident that if one is to use this test as an aid in differential diagnosis within the pelvis, a careful history and physical examination is necessary to exclude the presence of infection elsewhere in the body. It is to be remembered that infected sinsuses and teeth as well as acute rheumatic fever, tuberculosis, etc., cause rapidity of sedimentation. The chief physiological condition which increases the rate is pregnancy. This increase is gradual from the third month, until at the ninth month it is, according to Griffin¹⁵ (1934), five times the average normal. This change in rate above the normal entirely disappears by the fourth week postpartum.

In the differential diagnosis of conditions causing pain in the right lower quadrant the sedimentation test furnishes a very definite aid, particularly within the first forty-eight hours of the onset of symptoms. At this stage the chief concern of the clinician is to rule out or verify acute appendicitis for practically every other pain producing pelvic lesion will permit of some delay for observation in arriving at a correct diagnosis.

It has been repeatedly emphasized in the literature (Grodinsky, Lesser and Goldberger, and Smith) that the sedimentation rate remains approximately normal in acute appendicitis for at least the first forty-eight hours from the onset of symptoms, and during the catarrhal, suppurative, and even gangrenous stages of this pathology. Increased rates are observed only in empyema, localized abscess or general peritonitis. Records made on the surgical service of the Roosevelt Hospital support these observations.

Frequently, and in private practice especially, cases of acute salpingitis are seen sufficiently early that the swollen tube has not become indurated enough to be recognized as a palpable mass, and the bimanual examination reveals only tenderness and spasm. In nearly all of these cases the sedimentation rate is already markedly increased, (50 to 100 mm. in

an hour.)

Thus even with all clinical and physical data at hand this test may be a real deciding factor in differentiating the acute appendix from the early acute tube. That these conditions produce no such constant variation in the total white blood count nor in the polymorphonuclear cells by the ordinary count or by the Schilling or Arneth indices has been repeatedly demonstrated (Grodinsky,8 and Lesser and Goldberger[†]).

The most rapid sedimentation reading recorded by Lesser and Goldberger in seventy-five cases of acute catarrhal suppurative, or gangrenous appendicitis was fifteen mm. in one hour while the white blood count varied from 7,000 to 29,000 and the polys from sixty per cent to ninety-three per cent. In cases of acute salpingitis, the sedimentation rate is seldom below fifty mm. and frequently up to one hundred mm. in one hour, while the white blood cells are from 7,000 to 30,000 and the polys from seventy per cent to ninety-two per cent. Grodinsky, reading the sedimentation in time rather than rate, found that in forty-three acute and subacute appendix cases the average was 115 minutes while in the average acute tube, the time was thirty to sixty minutes. The leukcocyte and poly counts (by Schilling index) showed no characteristic differences in the two conditions.

As soon as the pathology in question produces a palpable mass, no such dependence can be placed upon the sedimentation test to differentiate appendiceal from tubal involvement, for the appendix abscess may have a rate equal to that of

the pus tube, and the diagnosis must be made from clinical history and physical signs. However if the appendix can be ruled out in any case of pelvic mass then again the sedimentation test becomes an important adjunct in ascertaining the nature of that mass.

Here one must consider salpingitis, unruptured ectopic, twisted ovarian cyst, hemorrhage into a large Graafian folliele or eyst, and painful ovarian swelling related to ovulation. It is obvious in this group that the history and pelvic examination are by far the most important factors in making the correct diagnosis while temperature, blood count, Aschbeim-Zondek test, and sedimentation rate only

help to influence the opinion.

The swollen inflamed tube will consistently have a sedimentation rate of from fifty to one hundred nun, and a time of thirty to fifty minutes while the unruptured ectopic pregnancy with none or very little blood in the peritoneal cavity will have a rate between twenty to thirtyfive mm, and a time of one hundred to one hundred and twenty minutes. The twisted ovarian cyst may have a very high sedimentation rate if there has been much interference with the circulation of the tissue, while the hemorrhage into the follicle or cyst and the painful ovarian swelling usually cause no increase in the

Thus far we have endeavored to show that the sedimentation test is invaluable in helping to differentiate pelvic inflammation from other lesions, but this test also offers the gynecologist a much more important service in assisting him to prognosticate the degree of healing in valpingitis or postabortional infectious, and in giving him an accurate indicator as to the proper time to operate.

Previous to the use of this test we depended chiefly upon the temperature enrye and leukcocyte count for this information. Then repeatedly cases of pelvle infection were allowed out of hed too early and had relapses, or operations were done in the "too acute" stage resulting in excessive operative trauma and stormy convalescence. We found the temperature curve and leukcocyte count returned in normal often many days before the sedi-mentation rate had been appreciably reduced restore by adopting the rule of

م ال (جانة

not allowing cases of acute salpingitis out of bed until the sedimentation rate falls below thirty mm. in an hour (this is equivalent to a sedimentation time of sixty minutes) we have had practically no relapses. Similarly by adopting the same figure above which we would not operate upon chronic tubal disease we seldom enter the abdomen in the "too acute" stage and postoperative convalescence is far smoother. Likewise the chance of practicing more conservative surgery is enhanced. This is more especially true if one is contemplating such work as salpingoplasty or re-implantation of the tubes at the uterine cornua for sterility. By following this same rule in fibroid cases both hysterectomy and myomectomy may be done with less operative risk.

We have not discarded the leukcocyte count and differential but we have added to it the sedimentation test, and of the two we feel the latter offers us more accurate information in both diagnosis and therapy. Its technic is simple and not a burdensome task. We feel that by strict dependence upon the sedimentation test in guiding our therapy both for palliative and operative measures, we have vastly improved our care of every patient on the service.

Gonococcus Complement Fixation Test

Every gynecologist is frequently confronted with the problem of determining whether or not a case of tubal infection is of Neisserian origin, and even more often he may be called upon to say whether a proven case of gonorrhea is active, latent, or cured. In such decisions every scrap of positive or negative evidence is welcome.

With a desire to learn from our own experience just how valuable the gonococcus complement fixation test might be in aiding us to determine a correct diagnosis or evidence of cure in pelvic infection, we began about eighteen months ago to do this test along with the usual Wassermann on all ward admissions.

Technic. Three tubes are set up for each test. The first contains .05 c.c. the second .1 c.c., and the third (the control) .2 c.c. of undiluted patient's serum. To each of these is added .3 c.c. of saline. Then to the first and second tubes (the

third tube being the control) is added the antigen according to the titration marked on the vial by the manufacturer. (We have been using Parke, Davis & Co., Polyvalent Gonococcus Antigen and the usual amount added is from .1 c.c. to .15 c.c. of a 1:20 dilution of this antigen.) This antigen has been found to be quite stable and retitration is not usually necessary. After adding the antigen, the tubes stand at room temperature for ten minutes. Then is added to all three tubes .2 c.c. of a 1:10 dilution of guinea pig serum as a complement. The tubes then stand in the ice box over night. The guinea pig serum complement is obtained by drawing from the heart ten c.c. of blood and by using only this amount from each animal; they are not killed but used repeatedly for this purpose. Next morning to each tube is added .2 c.c. of anti-sheep amboceptor (Parke, Davis & Co.). (This too is titrated and dilution is according to the titration.) Next is added .2 c.c. of five per cent sheep cells in saline. tubes are then placed in a water bath at 37.5 degree centigrade until the control tube clears (usually about 45 minutes) and the final reading is made about one hour later at room temperature. Readings are made according to the degree of clearing as one, two, three, and four plus.

Brunet and Levine¹⁶ in reporting recently on 1000 gonococcus complement fixation tests on female patients stated their belief that a negative reaction in some cases with positive clinical evidence of disease does not dispute the specificity of the test. The gonococcal antibody is at its height in four to six weeks after infection in untreated cases, and begins to disappear rapidly as a case yields to treatment. They also feel that the antigen used in many laboratories is insufficiently sensitive and that a negative reaction in a case with suspicious clinical symptoms cannot be taken as an indication of the absence

In our own experience we encountered several early cases with negative fixation test and positive smears in which a week to ten days later the fixation reaction was four plus. We therefore wish to emphasize the necessity of repeated tests in early suspicious cases.

of gonococcal viability.

Brunet and Levine, 16 and Retzlaff 17 and others have found that in the presence

of seropositive syphilis the gonococcus fixation test will give positives in a few cases in which gonorrhea does not and has not existed Brunet and Levine noted this in nine to ten per cent of their luctic

We have had thirteen cases with three and four plus Wassermann reactions who have also had positive fixation tests. Seven had one plus, two had two plus, one had three plus, and three had four plus fixation tests. All but one had negative smears, seven had elimical evidence of gonorrheal infection while six had no history or clinical evidence of such infection. Thus even this small group would seem to bear out the observation that in the presence of seropositive syphilis the gonococcus fixation test cannot be regarded as specific in indicating the presence of Neisserian infection.

However in the absence of a positive Wassermann, the fixation test has been found to be sensitive and dependable if carefully prepared antigens are used. The intensity of the complement fixation scens to have little if any relation to the location of the disease, but to depend chiefly on the time factor from the onset of the infection and therefore upon the amount of specific antibody in the blood With the present antigens it has been shown that the antibody appears in the blood in sufficient quantity to give positive reactions within the first week and often before the disease can be clinically recognized On the other hand, Retzlaff, 17 Brunet and Levine, 16 Inone and Nagasaki 18 have all shown that the antibody disappears from the blood in from one to six weeks after all organisms have been eliminated

In the absence of syphilis, persistent positive fixation reaction, regardless of its intensity, means the presence of active organisms and disease. Even a one plus reaction, if repeatedly obtained, must be so regarded. However a negative reaction must not be considered as evidence that infection does not exist, since it is known that a number of cases with definite gonococcal activity show negative results. This has been explained as due entirely to the use in the test of a strongly lytic complement unit, which renders negative what otherwise would be weakly positive tests. A more widespread use in labora-

tories of purer antigens will in turn permit employing complement units of reduced lytic potency, and thus gradually the fivation test will be markedly improved in this respect

During the past year we have had seventy-five cases with positive gonococcus complement fixation tests, thirteen have had positive Wassermanns so that sixty-two may be regarded as having had scrological evidence of gonorrhea these forty-three had clinical proof of the disease, ten by positive smears and thirtythree by physical findings, while ninetecn had no clinical evidence of infection According to the intensity of the reaction seventeen were one plus, twelve were two plus, thirteen were three plus, and twenty were four plus Of the ten cases with positive smears two were one plus, two were two plus, two were three plus, and four were four plus

In our experience the positive gonococcus complement fixation test became negative within a few weeks after obtaining consistently negative smears provided there had been no tubal involvement With palpable adnexal pathology present, the test often remained positive long after obtaining negative smears and in some chronic cases continued to give positive reactions until surgical removal of the diseased tubes had been accomplished. In acute salpingitis which cleared up rapidly leaving no palpable evidence of tubal involvement the fixation test became negative within two months. No correlation could be established between the location of the lesion and a positive test as the reaction seemed equally sensitive in all groups We also believe that in chronic adnexal pathology the positive test will definitely differentiate the specific from the nonspecific infections but that at present in our laboratory the negative test cannot be depended upon to so differentiate these cases

Frei Test for Lymphogranuloma Inguinale

The Frei test for lymphogranuloma inguinale is rapidly finding a place of importance among the diagnostic procedures of many gynecological services A discussion of the clinical recognition and treatment of this disease is not within the scope of this article but for those inter-

ested in this phase of the subject we refer to the splendid articles of Cole,¹⁹ DeWolf and VanCleve²⁰ in Cleveland in which a complete bibliography may be found.

The inguinal adenitis in the male, and the elephantiasis of the vulval and perianal tissues with the multiple fistulae and frequent rectal stricture in the female have all been described for many years and variously attributed to tuberculosis, syphilis and other causes. The etiological agent has not been identified except as a filterable virus, which can be transmitted to animals and through animals back to humans.

In 1925 Frei²¹ reported an intradermal test for lymphogranuloma inguinale, and all subsequent workers in this field have testified to the specificity of this test. Chancroidal ulcers and adenitis which might be confused give a negative Frei test and can be more positively identified by the Ducrey bacillus in smears or by the Ito-Reenstierna reaction, also a specific intradermal test.

Frei and subsequent workers secure the material for the antigen by aspirating the pus from a suppurating unopened node in a patient with lymphogranuloma inguinale who has also never had syphilis or chancroidal infection. This material is diluted 1:2 or 1:4, depending upon its consistency, with sterile saline solution. It is sterilized at sixty degrees centigrade for two hours one day and to the same temperature for one hour the succeeding day, after which it is tested for sterility and put up in ampoules. The antigen is then tested on known cases of this disease, but not upon the same case from which the material was obtained, and the reaction should be positive in these cases and negative in normal controls.

For the test an intradermal (not subcutaneous) injection of .1 c.c. of the antigen is given and the reaction is read in forty-eight hours. A red papule, 6 mm. or larger in diameter is regarded positive, and the measurement should not include the faint erythematous blush which often surrounds the papule. A positive papule may be larger and may umbilicate and even suppurate. For this reason in the female it is desirable to make the test on the thigh rather than the arm, as the papule often persists for some weeks and may leave a scar. This reaction is of an

allergic nature, is present within ten to twenty-one days after the adenitis appears and probably remains positive throughout life.

Hellerstrom²² has shown that antigens made from the brains of monkeys infected through subdural injection, give the same specific Frei reaction when used on humans as when the human antigen is used. Working along this line, Grace and Suskind²³ at Cornell Medical College have developed a mouse brain antigen which is more highly potent than that made directly from the same human material used in the preparation of the brain antigen.

We are greatly indebted to Doctor Grace for furnishing us the antigen used on our service. This antigen is a ten per cent emulsion of infected mouse brain and for each test .1 c.c. is injected intradermally, using a one c.c. tuberculin type of syringe with a 27 gauge needle. If positive, the raised papular reaction is noted in from forty-eight to seventy-two hours. If negative, no reaction occurs and if one uses an injection of a similar emulsion of normal mouse brain as a control, no reaction appears. Quite recently one of the commercial laboratories (Lederle) has begun the manufacture of a potent mouse brain antigen and it is now available to the profession in syringes ready for use.

Particularly in the female the location of the lymph nodes involved depends necessarily upon the seat of the primary lesion. If this is located high on the vulva the inguinal nodes may be swollen; if lower around the fourchette or within the vaginal orifice, the deeper pelvic nodes and those around the rectum become infected, later resulting in palpable pelvic masses and stricture. Extensive vulval and perianal involvement is readily recognized, but not infrequently the primary lesion may be small, of short duration and, especially if it is situated within the vaginal tube, may readily be overlooked. If such cases have considerable swelling of the deeper and higher pelvic nodes the condition may easily be mistaken for the induration of parametritis or tubal infection. It is in such instances that the Frei test is of inestimable value in recognizing the true character of the pathology, and it is for this reason that we venture to include this test in our consideration of laboratory aids in the diagnosis and

treatment of pelvic inflammatory disease. The following case from our service

serves to illustrate this point:

H.G.M., an American white woman, age thirty, was admitted with a history of increasing constipation, pelvic pain, and a sense of mass in the rectum of three months duration with blood in the stools on two occasions and ten pounds loss in weight down to ninety-two pounds. She denied gonorrhea or lues. Pelvic examination revealed normal external genitalia, vagina, and cervix; uterus normal in size and pogition; right adnexa negative and the left pelvis containing a hard tender mass of induration fixed in the fornix and high around the rectum and pelvic wall, Sigmoidoscopy up to twenty cm. revealed no growth but indicated that the rectum was in part fixed to the mass.

On admission the temperature was normal and the sedimentation test sixteen mm. in an hour. The other laboratory tests, including gonococcus fixation and Wassermann, were negative. Barium x-ray of the colon was negative for obstruction or growth. Within four days the temperature was between 101 and 103° F., the sedimentation test 101 mm., the w.b.c. 13,000, polys 94, and the left pelvic mass became rapidly larger with evidence of fluctuation in the culdesac.

Through a posterior colpotomy incision was obtained a quantity of serosanguineous fluid from which was grown a pure culture of long-chain, non-hemolytic streptococcus. The character of this fluid and the high perirectal induration noted on examination through the colpotomy incision made us suspicious that the infection had not originated in the tube. A Frei test done the day of this operation was strongly positive in forty-eight hours, the papule being ten mm. in diameter and four mm. in height. The patient has since been receiving tartar emetic intravenously and the mass now is less than half its original size.

We feel that in the past, without a knowledge of the pelvic pathology of lymphogranuloma inguinale and the Frei test, this case would have been diagnosed among the general group of pelvic inflammatory disease. Lymphogranuloma inguinale is not a rare disease. Two cases are on our service at the present time. Frei antigen is now available to all, and we therefore strongly urge the use of this test in all suspicious cases, or in all instances where the etiological factor in the pathology of pelvic induration is not clearly demonstrable.

Conclusions

In conclusion we wish to restate our conviction that the sedimentation test is a most valuable aid in the diagnosis of early acute infections in the pelvis and particularly in the right lower quadrant; that it is an indispensable adjunct in estimating the progress toward cure in all types of tubal disease and pelvic cellulitis; and that it is the most accurate indicator we have of ascertaining when an operative case of salpingitis, tumor, or other chronic inflammatory pathology, is in favorable condition for surgery.

We believe that the gonococcus complement fixation test merits a more general use in accurately diagnosing types of pelvic infection and in determining the latency or cure of Neisserian disease; and that the Frei test for lymphogranuloma inguinale, with its antigen now readily obtainable, should rapidly become a necessary part of the diagnostic equipment for properly investigating obscure intrapelvic lesions on every gynecological service.

Discussion

Dr. C. J. Marshall, Binghamton-I have had no experience with the Frei test and very little with the complement fixation test for evidence of gonorrhea.

A study of the sedimentation time was made in twenty-five cases of pelvic infections, urethritis and vaginitis, at the Binghamton City Hospital while under the Elliot treatment. The number of tests varied from two to fourteen and Linzenmeier's method was used. Counts falling below 12,000 and with a normal differential, usually showed a normal sedimentation rate. Pelvic pain in such instances was finally found to be due to conditions other than inflammation lesions. However, with a history of chronic salpingitis and a similar count three cases showed an increased rate. This, of course, suggests an active stage of chronic inflammation. Other cases with fairly definite clinical evidence of pelvic inflammation, but with a low count, had a rapid rate, thus indicating that the sedimentation rate, at least in some instances, is a better criterion of body reaction to infection than ordinary routine blood counts. Another thing brought out in our series was that in pelvic inflammation, combined with a four plus complement fixation test for syphilis, the sedimentation rate was extremely fast, going as low as fourteen minutes. On the whole, however, the sedimentation rate correlated

well with the blood count, a high count with a high percentage of leukcocytes being accompanied usually by a rapid sedimentation rate which decreased with the blood count.

When operative procedures were followed, it was noted that, at least in some instances, the rate of sedimentation corresponded to the extent of involvement, that is, a large abscess or ruptured abscess had a more rapid rate than a smaller localized accumulation of pus. And this may be used as a means of differentiation, since an acute uncomplicated appendix may have a relatively normal rate. Furthermore, unruptured ectopic pregnancy is apt to have a normal rate.

Thus, the sedimentation test may assist in making a differential diagnosis, but its real value appears to be in following the progress of a case. The Schilling count was not done in our series, but from subsequent observation, it is obvious that the two tests would afford valuable information.

As a result of the observations made in our series, the conclusions arrived at are similar to those mentioned by Dr. Peightal, namely, that the test is important-1. In making a differential diagnosis. 2. In assisting in deciding the optimum time for operation. 3. In following the progress of a case undergoing medical treatment.

POST GRADUATE INSTITUTE TO BE HELD

A Post Graduate Institute, offering an intensive and interesting study of the newer work in the field of cardiovascular and renal diseases, will be conducted by the Philadelphia County Medical Society during the week of April 20 to 24, inclusive.

The program, to be held in the Bellevue-Stratford Hotel, Philadelphia, has been designed to meet the needs of all members of the profession, but particularly those in general practice. Physicians from all parts of the eastern and east-central United States are invited to attend.

Lecturers, about thirty in number, have been selected from among the foremost teachers in this great center of medical education. The medical faculties of the University of Pennsylvania, Jefferson, Temple, and Woman's Medical College of Pennsylvania, are represented on the program. While approaching the subject from specialized viewpoints—those of the physiologist, cardiologist, pediatrician, surgeon, roentgenologist, bacteriologist, internist-the presentations will be of a strictly practical nature, and should be of real value to the general physician, who finds cardio-renal conditions occupying a large proportion of his time.

The Philadelphia County Medical Society, in conducting the Post Graduate Institute, is meeting the demands of many physicians who have felt the organized profession should provide them with this type of opportunity for keeping abreast of medical progress and thus maintaining the highest standards of medical service. The only charge is a \$5 registration fee to cover the Institute's expenses. It is hoped to make the event an annual one, giving special attention each year to a different subject.

PULMONARY TUBERCULOSIS

Serial Roentgen Studies in Superinfections

HLNRY K TAYLOR, MD, FACP, New York City From the Department of Roentgenology Sea View Hospital, New York City

Clinical observation and serial roentgenographic study of the adult type lesions in pulmonary tuberculosis (superinfections) permit of a classification which is based on a qualitative component, irrespective of the size of the lesion Roentgen study has revealed that tuberculosis lesions are either exudative or productive in character from the earliest time that patients come under observation The healing manifestations of these lesions, demonstrable on the roentgenogram, characterizes the lesion and permits of a division into five types. The exudative lesion may (1) resolve completely and leave no traces in the roentgenogram, or, (2) it may resolve incompletely, leaving a few fibrotic strands as the only residue of a previous inflammatory process, or, (3) it undergoes necrosis with cavity formation The productive lesion may present itself as (1) small nodules or fibrotic strands or a combination of both, or (2) fibrosis with small excavations resembling a bronchiectasis

Exudative Lesions

1 Complete Resolution (beingn) This is an acute lesion presenting few and no alarming symptoms clinically, and is often overlooked The symptoms may be no more marked than an ordinary cold and disappear in a few days. The lesion usually escapes detection because of none or infrequent roentgen examinations when few clinical symptoms are present Hemoptysis is present in about forty per cent of these cases and this symptom usually-not always, unfortunatelycalls for a roentgenographic examination of the chest The findings are commonly those of a coalescent multilobular area of decreased aeration, exudation or consolidation, varying in size from a small patch to a lobe or lung When resolution of this lesion is complete, which requires from six weeks to six months, there are no roentgen evidences of a previous inflammatory process During resolution annular shadows are sometimes observed which may be mistaken for cavities. These annual shadows disappear as resolution progresses True cavities which close spontaneously usually leave some cvigences (of fibrosis) in the rountgeno gram (Figs 1A and 1B)

2 Incomplete Resolution — Residual Fibrotic Strands (benign) The roentgen findings are similar to the one just de scribed Resolution requires more time six to eighteen months. When the exudative lesion has completely resolved there is a residue of a few fibrotic strands, the only evidences of a previous inflammatory process Here also annular shadows may present themselves during the process of resolution and be mistaken for cavities, which disappear as resolution progresses (Figs 2A and 2B)

3 Necrosis with Cavity Formation (malignant) This type of pulmonary tuberculosis accounts for the mortality The lesion resembles the two above de scribed types Instead of resolution, caseation with cavity formation results. This is nature's attempt at healing-localization of the lesion with expulsion of the products of the infection Bronchogenic spreads to other portions of the lungs may occur The cavities serve as sources of tubercle bacilli. The spread to the same or contralateral lung may be benign or malignant, depending for the most part upon the dosage (Figs 3A and 3B)

Following through to the end stages, this lesion may terminate in one of two wavs (1) the lesion may excavate itself and leave one or more cavities (Fig. 4A), producing no deformity of the thoracic and mediastinal structures, or (2) after excavation, secondary changes occur such as retraction of the lobe, or lung, bronchostenosis, fibrosis, emphysema, deformation of the thoracic and mediastinal structures (Fig 4B)

From the onset to the terminal stage of a malignant exudative lesion many changes become apparent-consolidation, necrosis, cavity formation, fibrosis, bronchostenosis, atelectasis, deformation of

thoracic and mediastinal structures, etc. Because of these varied developmental changes of this type, the nomenclature is replete with descriptive terms for this lesion, such as, chronic ulcerative, fibrocaseous, ulcero-caseous, mixed cavernous, etc.

Productive Lesions

1. Fibrosis (benign). This lesion usually starts in the apex of the lung and

is often bilateral. Small dense nodules and fibrous strands are found. At times, only the nodular lesion is apparent. This type is not preceded by a demonstrable exudative lesion in the roentgenogram. The process may be limited to the apices or upper lobes and show no progression (Fig. 5A) or progress slowly (Fig. 5B) and eventually involve the major portions of both lungs. These patients are usually well, present few or no symptoms

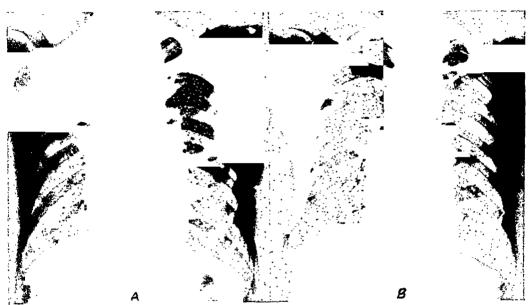

Fig. 1. J. R., negro, male, age 47: A—coalescent exudative lesion in right upper lobe; B—four months later, complete resolution with no traces in the roentgenogram (benign exudative).

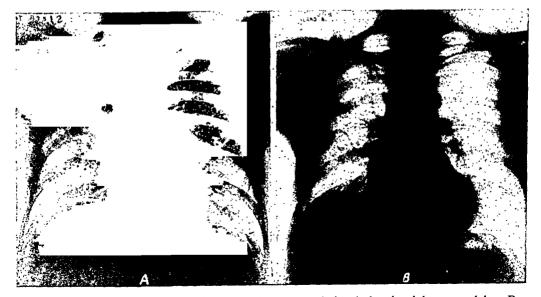

Fig. 2. R. B., white, male, aged 37: A—coalescent exudative lesion in right upper lobe; B—eight months later, incomplete resolution—residual fibrotic strands in basal and axillary portion of right upper lobe (benign exudative).

and may be unaware of their tuberculous process, until some complicating lesion develops, such as, emphysema, laryngeal or intestinal tuberculosis

2 Fibrosis With Cavity Formation (malignant) At times, the nodules in the type just described, coalesce, cascate, and form numerous small cavities, resumbling a bronchicctasis (Fig 6) When

this occurs the lesion should be considered malignant. These small excavations are sources of tubercle bacilli. A gradual extension of the lesion may occur by frequent bronchogenic spreads.

Graphically, the types may be sum-

Benign—Exidative complete resolution resolution with residual fibratic strands

Fig 3 R Y, negro female agod 27 A—coalescent exuditive lesion in left upper lobe B—two months liter, central necrosis with cavity formation (mulignant exuditive). There is an exuditive spill in the right base.

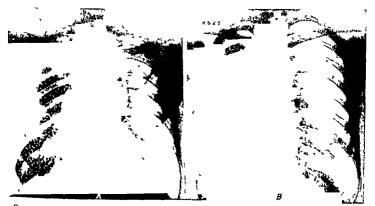

Fig 4 A—G F, white male, aged 52 Lungs show cavities, no deformities, two year history (malignant) Sputum always positive Gaffky 4 No temperature B—HT, white, female, age 21 Retraction of chest and lung with deviation of the traches, heart and mediastinum to the right, four year history (malignant) Sputum positive Gaffky 2-4 No temperature

Productive; stationary: progressive.

Malignant—Exudative; cavitation with and without deformity. Productive; coalescence of nodules with cavity formation.

Miliary tuberculosis is not included in the types described, for it is a complication, a rupture of a caseating focus with wide dissemination of many organisms by the blood stream.

It is obvious that the roentgen study reveals a qualitative element in addition to the quantitative component of a tuberbe described as acinous, lobular, multilobular or lobar, discrete or coalescent, local or general, unilateral or bilateral, and minimal, moderate or extensive.

Recently, Brown and Sampson² described a tentative working classification, which in conjunction with the color of the individual and the size of the lesion, minimal and advanced, also depends upon the qualitative component to aid in the treatment. They divide their advanced cases into exudative and proliferative

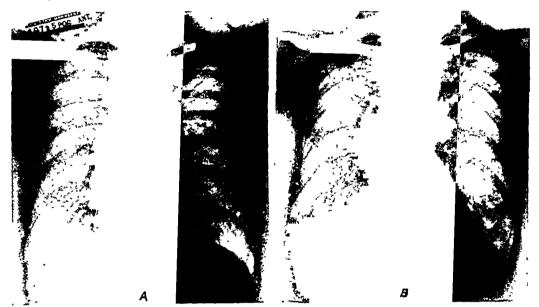

Fig. 5. A—J. L., white, male, aged 34; Fibrotic strands with numerous small nodules in apices. No progression of the lesion in two years (benign productive—stationary). B—P. K., white, male, aged 57. Fibrotic strands and nodules in upper lobes. Gradual extension of the lesion—five year history (benign productive—slowly progressive).

culous lesion. The National Tuberculosis Classification is based on the quantitative element of the lesion, depending upon the area of lung involved. The National Tuberculosis Association recognizes that a qualitative element exists, admits it may have a clinical significance, particularly in relation to prognosis and treatment, but deems it difficult and perhaps inadvisable at the present time to include this feature in its classification. I believe that the qualitative component is the more important and should be the dominating factor in the classification, while the quantitative element is of lesser importance and should receive secondary consideration. In addition to the qualitative element of the lesion, the anatomical description as well as the quantitative component may be utilized. The lesions may

groups, each with and without excavation, and their tendency to remain either stationary, progress or retrogress. To quote Brown and Sampson.

All patients with the exudative type of disease should be considered to be in a more serious, a more rapidly changing, a more acute condition. In a certain number the condition improves very rapidly but in others it progresses just as rapidly.

The phrase condition improves very rapidly certainly must refer to resolving benign lesions. They also show ninety-two per cent alive at the end of fifteen years in a group they designate as minimal, with no cavity formation, where there has been no surgical intervention. Certainly, this latter group must have had benign lesions.

Investigation of the literature reveals

that the qualitative element of the lesion in pulmonary tuberculosis is known, but is not utilized. In 1925 Bendove³ described resolution and healing in pulmonary tuberculosis and quoted Krause⁴ (1922) on the healing and disappearance of tubercles. In 1931 Ornstein, Ulmar, and Dittler presented a clinical classification of Pulmonary Tuberculosis, and Shipman independently, presented a classification quite similar to the one of Ornstein, Ulmar, and Dittler, ^{5,6}

Classifications depending upon autopsy material, while valuable, give the terminal stage, omitting information as to progression or regression. The roentgen examination permits of scrial studies, the qualitative as well as the quantitative elements, practically throughout the entire course of the disease.

The above subdivision of pulmonary tuberculosis into various types is based essentially on the clinical classification of Ornstein, Ulmar, and Dittler. The various types of pulmonary tuberculosis presented above are not serial changes of one lesion. There is no interchange of the lesions. Clinically and roentgenographically, each type runs its own course. More than one type may be present in any one individual, depending upon spills, contacts, dosage, etc. The presence of a cavity always indicates a malignant lesion.

What is the value of this classification? It divides all cases of pulmonary tuberculosis into two main groups. These two groups are designated as benign and malignant. Expressed in other words, the former* requires no active collapse therapy measures (nonsurgical) while the latter does (surgical). The benign group has practically no mortality rate. These lesions run mild clinical courses and their prognosis is good. Surgical procedures in this group only help to inflate statistics which are only apparent and not real; for the end result, as far as the patient is concerned, would have been the same in the absence of any surgical procedure. The malignant group on the other hand has a high mortality rate. These lesions run stormy courses, metastasize, and spread. These lesions are the only one which require, and are actually benefited by, collapse therapy measures. The prognosis in the untreated case is bad. Statistics show that over fifty per cent die during the first year.

Fig. 6 W. G, white, male, aged 58, Fibrosis with numerous small exeavations in right upper lobe; eight year history (malignant productive).

Serial roentgen studies reveal whether a lesion is benign or malignant. This information aids in determining prognosis and treatment, and helps correctly to select cases suitable for collapse therapy. With the increased use of collapse therapy. measures, proper selection of cases is essential, rather than to have the indiscriminate application of procedures in cases in which no such therapy is indicated. The knowledge of the quality of the lesion is essential if the various collapse therapy procedures are to be correctly evaluated. The indications for collapse therapy are gradually being enlarged so that a bilateral pneumothorax, or a partial bilateral thoracoplasty, or a thoracoplasty on one side and a pneumothorax

^{*} The induced pulmonary pathology in superinfections depends upon dosage and virulence of the tubercle bacilli and the response on the part of the host. If, in a given individual, a benign exudative lesion is found, it essentially represents the response to a certain dosage. A malignant lesion may develop in this individual a subsequently, representing a response to a greater dosage. Because of this, individuals with benign exudative lesions should not be hospitalized in tubercular sanatoria, unless strictly isolated.

on the other, combinations of collapse therapy procedures, are becoming more common.

From the clinical standpoint, with the aid of the roentgen studies, this classification is applicable in most cases in a comparatively short time, usually less than three months. A benign exudative lesion cannot be definitely determined from the first or a single examination — serial studies are necessary. This classification becomes of considerable importance in determining management and delivery of a pregnant woman in the presence of a pulmonary tuberculosis. Experience has shown that pulmonary tuberculous lesions -follow a given course irrespective of the pregnancy. The benign exudative lesions undergo resolution in the same manner 'as in nonpregnant cases. This group presents no mortality rate. A comparison of pregnant with nonpregnant individuals ill with a malignant type pulmonary tuberculosis, bearing in mind age groups, duration of illness, etc., shows about the same mortality rate, which is high.

Summary

- 1. Serial roentgen studies permit of a division of superinfections into two groups, benign and malignant, and aid in determining prognosis and treatment. The benign group (nonsurgical) requires no collapse therapy, while the malignant group (surgical) is the only one which requires, and is benefited, by collapse therapy.
- 2. Superinfections are either exudative or productive in character.
- 3. The exudative group presents two benign and one malignant lesion.
 - 4. The productive group presents one
- benign and one malignant lesion.
- 5. The value of the subdivisions into various types lies in: (a) aids in prognosis, and (b) proper selection of (malignant) cases for collapse therapy.

Only fifty per cent of the 4,000 or 5,000 nurses in Brooklyn are capable of giving adequate care, Dr. J. A. Curran, chairman of the Kings County Committee on Nursing, said on Dec. 10 at a meeting of the women's auxiliary of the Kings County Medical Society.

Dr. Curran, in making an advance report, said his statements were based on a series of carefully prepared questions already answered by more than two hundred borough doctors and specialists. The committee desires answers from one thousand on nursing before making public its final report.

"About half of the nurses in Brooklyn are graduate nurses," Dr. Curran said the report revealed. "About one-third of the maternity cases in the borough are superintended by physicians. A nurse assists in seventy-five per cent of the cases.

"Forty-three per cent of the patients in acute illnesses had to shift from graduate to unqualified nurses, and seventy-two per cent of the patients in chronic cases. These shifts were chiefly due to financial reasons.

"Think what this means. In acute illness the need for skilled attention is great enough and with inadequate nursing care in seventy-two per cent of the chronic cases the doctor is hamstrung by inefficient assistance. If the grade of nursing care is sliding downhill, then medical care is retrograding with it."

The present program of school work is too heavy for little children, in the opinion of Dr. Nathaniel Preston Brooks, of Croton-on-Hudson, and causes nervous and mental fatigue. In a paper published in the Medical Record he notes that children of six are required by law in New York State to attend school thirty hours a week instead of an efficiency-maximum of fifteen hours, and twelve-year-olds are doing up to forty-five hours of school and home studying when the maximum should be twenty-two hours.

EDITORIALS

The American Foundation Studies in Government

We are prone to be "foundation shy ' We fear anything and most things which purport to be in the interest of the "betterment of mankind," and which comes to the public or to us on the letterhead of a foundation Too often physicians have learned of the results of studies and surveys in which medical activity necessarily is a part as being completed without consultation with the profession. It has also been usual for the officers and employees of foundations to publicize addresses and articles advocating medical reforms without having first consulted professional opinion or giving the professional viewpoint thoughtful consideration, and a place in the publicity Nor have we had any part, as a profession, in these studies or surveys

Recently we have had a communication from the American Foundation Studies in Government which was refreshingly new in its approach, in its breadth, and its goal. In the first place, their inquiry is addressed primarily to the profession itself. In the second place, they start their letter of inquiry with the statement "that the American Foundation has nothing to advocate" They have no "preconceived objective—as, for instance, state medicine, group insurance, voluntary or compulsory, ete." They further state, "Our studies are not even based upon a

conviction that any essential change in the present system is indicated" and "that the maintenance of the highest scientific quality in inclical care must always be a primary consideration." They go on to say, "Our general objective is to investigate the degree to which government may wisely serve its citizens within the limits of the parhamentary system."

As far as we have been able, we have investigated the sincerity of purposes of this organization, the people who are backing it, and some of their previous activities. We are satisfied as to their integrity of purpose and honesty of intention

We are therefore advocating that all physicians in this state to whom this inquiry is addressed should accord it a respectful reception and a considered reply. This reply should not be arrived at by collaboration, neither should it be a collective reply from an organized group of physicians. Let us give them what is asked, a personal reply, based upon personal opinion and experience

Never, heretofore, has the medical profession individually been asked what it thought of various proposed social reforms before they were advanced to the public for debate and adoption. Here is an opportunity long sought. Had the official agencies of organized medicine sent out this inquiry and put its official approval and stamp on the formularization and summation of the replies, the result would have been discounted by opponents of organized medicine, because of the very fact that the inquiry originated in organized medicine. The solutions of the problems presented, thus summarized, would have been designated as an officially imposed standpoint. On the other hand, organized medicine, have nothing whatsoever to do with originating this particular inquiry, can with equanimity recommend that physicians everywhere answer it from the standpoint of their own personal observation and knowledge, secure in the conviction that the unsolicited inquiry will disclose what organized medicine has heretofore held, and justify its attitude.

This inquiry, however, must not be construed as a means to justify the stand of organized medical activity. It is wholly an action on the part of the American Foundation. We, however, see here an opportunity to serve by telling this Foundation what we individually know. The New York State Journal of Medicine desires to allay any fears which our members might harbor because of the name of the organization from which the inquiry comes.

Here is a Foundation which is advocating nothing in the way of cheap medical care. They ask information from the one group in the body-politic which, by training, experience, and occupation, is in the best position to furnish it. Here is no set of lay investigators, sent into communities to query former patients and ask the public questions so as to formulate statistics which are to be used to bolster a preconceived idea on the delivery of medical care. Here is not even a formulated questionnaire. Here is a desire for a free expression of your own views. Give them freely, and thus serve both the profession and the community, and perhaps help confused legislators who will be swamped by propaganda from parties interested in schemes involving changes in the delivery of medical service to the people.

The Washington Plan Et Al

It is not unusual for lay organizations interested in "the betterment of mankind" and led by certain of the so-called social service groups, to reach a conclusion upon some scheme for delivery of medical care to the American people, and then popularize it. Finally, with addresses and through the public press, they propagandize it in an attempt to impose it on the whole medical profession.

Now we are being confronted with an almost analogous situation, except that the scheme for the delivery of medical care is propagandized from a rather small medical unit. There is in existence a socalled "Washington, D. C. Plan." It is in operation, sponsored by the Medical Society of the District of Columbia. It has been in operation but a short time. Viewed from the standpoint of a laboratory experiment, even the time element to study results and controls has not elapsed. Nevertheless the proponents for this plan, not satisfied with permitting its inherent virtues to become apparent, are stressing efforts to enforce its adoption upon all of us. Its originator is going into a new community to set it up there. Political efforts are being developed among the delegates to the A.M.A. to give it immediate attention, and an attempt is being made to form a local block among these delegates to sponsor the plan and secure for it A.M.A. support.

Irrespective of its merits and demerits, the Executive Committee of our Society has wisely taken no positive action to influence the New York State delegation. The principles of the Booth Report are still our guiding post. No one scheme is applicable to the whole country. Rural, suburban, industrial, and farming areas offer different angles to the problems of medical care, and each of these differ from the problems presented in large city areas.

Let the profession go slowly in adopting any general scheme. Because one of its features,—the collection of physicians' bills—may be attractive to most of us, is no reason to stop study on the

basic problem of finding a way to bring medical care to those prevented from obtaining it because of financial barriers.

Back to the Dark Ages

The annual anti-vivisection bill is a reminder of the dark centuries when scientists risked good name and life itself to perform the postmortem dissections which furnished the key to so many mysteries of the human body. The knowledge gained from those dearly bought studies brought incalculable benefits to the world. Today medical research is on the threshold of new discoveries which will abolish suffering, improve health and prolong life for millions more. All this the anti-vivisectionists propose to sacrifice to an emotionalism that feeds on shallow sentimentality and disregards the actualities of life.

The Doyle Act, like its predecessors, limits the ban on animal research to living dogs. Unfortunately the dog, of all animals, cannot be spared from the laboratory because of its structural similarity

to man.

The love which the anti-vivisectionists profess to feel for dogs is shared by many physicians. Doctors are not indifferent to the dictates of mercy, either. There is, however, an abnormality, a profound emotional imbalance, in the attitude which prefers dogs to children (as at least one well-known anti-vivisectionist admittedly does) and places the transient discomfort of a lower animal above the permanent welfare of the human race.

The defense of medical science is not the concern of the medical profession alone; and laymen should fight the Doyle bill as strenuously as physicians. If animal experimentation had been forbidden a hundred years ago there would be no toxin-antitoxin, no salvarsan, no insulin—to name only a few of the blessings that have come from research in vivo. If the dog is banned from the laboratory today, the door will be locked on new discoveries that hold equally great promise.

Life Blood of Quackery

A survey of the cheaper newspapers

discloses ample reasons for the persistence of quackery in spite of widespread efforts at public health education. The amount and quality of medical advertising in the yellow press are a revealing index of the taste and conscience of some of the most powerful newspaper publishers in the country. Notorious charlatans advertise cut-rate examinations at institutions that are known to gouge their victims mercilessly. Cures are promised for incurable conditions by dangerous or ineffective methods.

The code of medical ethics forbids physicians to advertise. Unfortunately it is binding only on practitioners who are affiliated with organized medicine and voluntarily subscribe to its precepts. Neither County nor State Society has any disciplinary power over the non-member physicians among whom quackery is principally found.

It is true that the Grievance Committee has authority to act in cases of flagrantly dishonest advertising but it is hampered by many of the impediments of legal procedure. The experienced charlatan knows how to phrase his "ads" to sound like one thing but actually say another.

The only effective cure of this rank evil is to forbid medical advertising altogether. The whole theory of advertising —to break down sales resistance by building up desire or fear-is out of place in medical practice, in which skill and not mass output is the basic criterion of success. The physician who advertises most extensively or cleverly is not necessarily the best equipped to treat disease. On the contrary, the most skillful practitioners have least reason to advertise because the demands on their time usually exhaust their capacity to serve. Advertising in medicine serves the incompetent and the unscrupulous. For the reputable physician it would mean increased overhead as he had to meet the competition of advertising colleagues with larger "ads" instead of greater competence.

The dental profession has banned advertising with benefit to the public and to reputable dentists. Similar amendment to the Medical Practice Act would give

the state a weapon of undoubted value against charlatanry in medical practice.

In the Best Tradition

Under Current Comment in our last issue we called attention to an item culled from Medical Economics of December, commenting upon "Research; Self-Supporting." It was here detailed that research, which is traditionally tied to the apronstrings of benevolent patrons, was giving evidence of declaring its independence, bolstered by royalites from profitable laboratory discoveries. Quoting William Alan Richardson, it was stated that "already three or four of the best known universities have seen their research laboratories turn into self-supporting branches either in whole or in part."

The thoughtful among us can not view with equanimity this trend to commercialize the research from university laboratories. If this trend continues and from more and more of them money research is obtained to bolster up depleted exchequers, it will lose to these research departments the unquestioned acceptance of their findings which, because of the un-commerical connotations of their published reports, they now enjoy. The loss in respect and authority which pharmaceutical research particularly in Germany, underwent immediately following and since the World War, is an analogy in point.

In view of this we commend the wisdom in the announcement of the School of Dentistry of Columbia University recently, (New York Sun, January 17, 1936) that the laboratory discovery of a desensitizer which was discovered by Dr. Leroy L. Hartman will not be patented, but will be published to the profession for its use.

It has always seemed to us a misconception of our ancient traditions to patent a discovery which helps to alleviate human suffering. We always thought that such agents should be at the disposal of the whole profession as soon as the research gave reasonable assurances that it had developed a new means of real therapeutic

value. Nor could we fail to contrast the action of the so-called laboratory research worker and his discovery, with the action of many reputable surgeons to whom it was granted the great privilege of having worked out a new surgical technic to eradicate a lesion, or the clinician who. by study and application of long periods of observation, had established a new clinical These latter,—both entity. surgeon and the clinician,-spend a great deal of their time and their own money travelling about the country, visiting clinics, hospitals, and medical societies, teaching their interested colleagues the new findings, or the new surgical technics. Neither do the institutions in which they work, nor do they personally gain any remuneration from this labor for human-Why should their case differ from that of the laboratory worker in the same institution?

We greet the action announced by Dr. Frederick Coykendall, the chairman of the Board of the University, as a proper step in the right direction, in keeping with the great traditions of medicine and of a great university.

The Legislative Arena

This early in the state legislative halls the trend of legislative activity cannot be predicted. The usual type of amendments to the Medical Practice Law are to be expected. Likewise the usual anti-vivisectionists will attempt to curtail experimental work. In this regard, it is even now evident that peculiarities develop. There is a novel situation developed this Assemblyman Doyle last year served as Chairman of the Public Health Committee which, after studying a similar bill to exempt the dog from medical experiments, refused to report the bill out. Nevertheless, Assemblyman Doyle this year is the sponsor of the bill. One may be pardoned for wondering at the motivation of such action.

The great effort to socialize us will probably again be made by Mr. Epstein. We await the introduction of his health

insurance measure. Measures to protect doctors' fees in the settlement of estates and other matters are developing.

Organized medicine, because of its standpoint that it will support anything and all things which are in the interest of the public welfare, has earned for itself a fine strategical position in the political arena. Let us not relax, but redouble our efforts to maintain this stand.

Writing in Lay Journals

The profession has condoned the action of those of us who write for lay publications when the motive is a public discussion of a medico-economic problem, or is an article purporting to instruct laymen along general lines. In most of such publications, by no stretch of the imagination can the author be accused of self-aggrandizement or specifically calling attention to himself.

The Principles of Professional Conduct, section 31, provides among other things, that "they shall not boast of cases, operations, cures or remedies, nor aid or permit the publication of any of the foregoing in the public print."

We call attention to section 31 because we feel that when medical men write for lay magazines published for lay consumption, detailing themselves, their operations, their cases and their cures, this constitutes, in our opinion, a violation. To our knowledge some of our professional friends have inadvertently fallen into this. To clarify the situation and sound a warning is our purpose.

It requires no great piece of mental activity to reason out to whom an article is addressed, who will be the readers. Then write so,—if write you must,—that good taste and our traditions, including our ancient code, are not violated.

The Annual Meeting in New York City

It is but natural that curiosity should develop regarding the plans in process of development for the next annual meeting. From all sources evidence is accumulating that this year's meeting will have unusual significance and results.

There are pending and originating in the respective county societies, questions of grave moment to us all. These questions are now in the stages of preliminary discussion in the component units of the State Society, and debate and decision upon them necessarily will take place in the House of Delagates. Our organization is truly democratic. Within its frame-work of parliamentary form, we shall work out an approach toward solution of many of our perplexing problems. Organized medicine has won for itself a high place in our body-politic, because we have reached our decisions mostly in the quiet calm of deliberate study, and have stood firm and strong against emotionally inspired appeals and propaganda. Progress has been slow but advances have been made, and ground is being gained in the solution of our problems. Many of our numbers have never observed the House of Delegates at work. The sessions are open to the members. Visit and observe.

On the scientific side, the preliminary work done by the committee headed by Dr. William A. Groat permits the prediction that both the exhibit and the sessions will be interesting and instructive. In addition this year, there is to be a Clinical Day, during which the clinical opportunities of New York City as a center of medical education, will be shown. This will afford the visiting profession not only an opportunity to visit clinics where specified demonstrations will be held, but by actual personal contact with laboratory workers, clinicians and surgeons, a mutual inspirational reaction may result, of benefit to both visitor and demonstrator.

It is too early to publish the names of distinguished foreign and American guest speakers. Acceptances are in hand to warrant the announcement that both the general assemblies and the section meetings are presenting an unusually high scientific standard of work.

Lastly, there will be the banquet for which Dr. Charles Gordon Heyd is de-

veloping a program whose announcement will probably overtax our ability handle the numbers desiring to attend. When applications for tickets to this function are receivable, it would be well for those who desire to attend to send in their reservations early. The committee announces that only one thousand tickets will be sold for this affair.

Last, but not the least important. Members should note that the Waldorf Astoria Hotel has made special rate arrangements with the committee. At the last meeting held in New York City, some of our members fearing the costs of registering as guests at the Waldorf, went to other hotels, and lost the advantages of which they could have availed themselves. It cost them more to stop elsewhere in the city. Our purpose is to again call this to their attention, so that they may profit by the arrangements made for them.

Reserve the dates from April 27 to the end of the week, for an unusual meeting from which to derive not only pleasure and relaxation, but instruction and stimulation. To attend its session will make of you a better doctor, and perhaps also, a happier man!

Metabolism of Malignant Growths

During the past thirty-five years, there has been an intensification in the study of cancer from the experimental viewpoint. The character of the investigation has been formulated in stages.1 From the earlier inquiries concerning the limits of transplantation of malignant tumors and a study of their hereditary nature, a step forward was made in the determination of their rate of growth and the means of inciting such growth. In recent years, attention has been directed toward the metabolism of the cancerous cell and toward the role of endocrine imbalance as a factor in tumor formation.2 These latter studies have added considerably to our

knowledge of carcinomata and allied malignancies.

Warburg³ has demonstrated that cancerous growths have an abnormal carbohydrate metabolism which results in a low respiration within the cell and a consequent high glycolysis. In this absence of oxygen, tumor tissue is capable of manufacturing ten to twenty times as much lactic acid as normal tissue does. Warburg feels, and he has been confirmed in his belief by Dickens,1 Glover,5 and others, that it is the interference with the respiratory activity of a growing cell which, from the standpoint of metabolism, gives rise to tumor formation. Where cell respiration is disturbed, the cell either dies, which is the usual sequela, or it is converted into a tumor cell. Further evidence of metabolic turbances in malignant tumors is shown by the increase of the lipoids and cholesterol, especially marked in cancer of the skin.

Of particular interest is the data derived from the study of carcenogenic hydrocarbons. Not all tars are capable of producing cancer. It was believed at first that the irritation resulting from the application of tar was the causative factor in the production of the ensuing growth. On further study, however, it was found that those hydrocarbons which possessed the property of causing a tumor formation, bore a close structural chemical relationship to cholesterol, ergosterol, vitamin D, bile acids, and most important of all, the male and female sex hormones.7 As early as 1907, Loeb8 was able

to produce uterine tumors in animals by using the secretions of the corpus luteum Conversely, Sussman² observed regressive changes in the cancer of humans who had solutions of the pituitary glands administered to them

As work continues, additional material is accumulated. This seems, to the casual onlooker, a conglomeration of isolated observations which bear no relationship one to the other. In time, nevertheless, these when fitted together, will complete the "jig-saw" puzzle which may lead to the eventual solution of the problem of cancer.

Syphilis. A Dual Problem

Venereal infections, because of the inherent social stigma which always has been attached to them, have confronted the health authorities with their most difficult problem in controlling the spread of communicable diseases In spite of the handicaps encountered, there appears to be a noticeable decline in the number of fresh syphilitic cases in the United States, if one can judge by the statistical report of one of our Commonwealths 1 This report, however, cannot be taken at face value, since the average physician still is reluctant to disclose a victim of syphilis to the guardians of the public health doctors feel that with the modern methods of therapy at their disposal they soon can rid the community of the menace which this disease entails This viewpoint on the part of the physician in charge of a syphilitic patient, is nevertheless not en tirely in accord with the newer experimental work

It was in 1911 that Nogouchi first succeeded in growing spirochaeta pallida in pure culture and was able, from this original growth, to reproduce the disease and then recover the original organism. No

one since has been able to isolate a culture of the organism of syphilis which continues to remain virulent 2 Many have attributed this failure to the presence of the evolutional or the granular form of the spirochaeta pallida, a phase in the developmental life of the organism which can neither be detected by dark field examination, nor by the staming of known infected The importance of the granular form of the causative agent of syphilis is accentuated by the fact that emulsions of human organs in the latent stages of the disease are capable of reproducing a luctic lesion when injected into the testes of rabbits

The equanimity of the practicing physician must be disturbed considerably when he is confronted with the fact that the final word has not been spoken anent the proper regime for the treatment of syphilis. The adherents of Neisser, who contended that immunity to a syphilitic infection was dependent upon the piesence of an active coexisting syphilis with living spirochaetes present somewhere in the body, have in recent years been strongly contested by the followers of the Chesney school, who maintain that an immunity to syphilis persists even if the original infection has been eliminated

If animal experiments can be proven to apply to man, the clinician must eventually know which of the above two theories is right If the Chesney doctrine is proven to be correct, the rapid sterilization of the tissues with spirochaeticides as now practiced may now have to be abandoned in favor of a means of therapy that will per mit the development of an immunity with which the patient can combat the serious. late manifestations of syphilis meantime, the close cooperation of physicians with the health authorities is essential for the isolation of potential sources of infection to the end that the incidence of syphilis may be reduced to a minimim

CURRENT COMMENT

IN HIS INAUGURAL ADDRESS, Dr. Charles E. Farr, President of the Medical Society of the County of New York, said among other things, "The aims of all of us are essentially the same. We desire to serve the people as best we may, to preserve the dignity of the profession, to eliminate abuses in our own ranks, to prevent encroachment from without and to aid in the progress of the art and science of medicine. . . Now the poor we have with us always, and their care justly belongs to the State until such time as poverty can be eliminated from the State. Physicians should not be asked to carry this entire burden, as for the most part, they have in the past, nor should they and the poor both be exploited by contract practice."

The New York Herald Tribune, January 19, 1936, quoting The Ethyl News, organ of the Ethyl Gasoline Corporation, says of the national wealth, that "the nation's 28,000,000 private homes are a denial of the assertion that sixty per cent of America's wealth is held by two per cent of the people. . . . The source of the 'fallacy' that the ownership of wealth is restricted to the comparatively few is traced to a very limited study of estates probated from thirty-five to seventy-six years ago." . . . "The desirable things,' it is pointed out, 'include 7,000,000 farms with their equipment and livestock and 28,000,000 private homes with everything which they hold, half in each case being owned outright by those who occupy them. Then there are hundreds of thousands of stores, shops, small enterprises; more than a million corporations, of which only 2,500 are large enough to be listed on any stock exchange, more than 45,000,000 individual deposits in savings banks and 10,000,000 memberships in building and loan associations with assets of more than \$8,000,-000,000; 113,000,000 life insurance policies representing actual assets of more than \$21,000,000,000; 20,000,000 privately owned automobiles and other assets whose totals run into unbelievable figures."

"Supporting this interpretation, the analysis says that during 1931 to 1934, the four worst years of the depression, the total national income paid out aggregated \$203,000,000,000, of which \$132,000,000,000, was distributed in wages and salaries and \$33,000,000,000 in withdrawals of shop-keepers, tradesmen and farmers who do not differentiate between wages and profits.

"'This 81.5 per cent of the total national income was paid out to these people; rents and royalties accounted for 2.5 per cent and dividends and other property income ac-

counted for 15.9 per cent,' says the publication."

From the New York Herald Tribune of January 12, 1936, we learn through the report of the American Hospital Association, published by its secretary, Dr. Bert. W. Caldwell, that statistics on hospitalization during 1935 were worse than in 1934. They reveal that 851,774 persons were domiciled daily in the country's 6,437 medical institutions. "One out of every sixteen persons, Dr. Caldwell said, was admitted to a hospital last year, pointing out that 7,465,201 patients were treated during 1935. This, he said, compared with 7,147,416 in 1934.

"Last year the nearly 7,500,000 patients passed 303,288,755 days, or 830,928 years in hospitals. Confinement in 1934 totaled

302,985,770 days.

"While the largest percentage of hospital patients sought surgical relief, he said, approximately 1,400,000 of the total patients for the year represented mothers and newborn infants. Babies born in hospitals numbered 715,000 in 1935 as compared with 701,143 the previous year."

In commenting upon the activities of the Rockefeller Foundation program, Mr. Max Mason, president of the Foundation, said in part, "The determination of sound Foundation procedure in the application of funds to the well-being of man becomes unusually difficult when increased opportunity and need coincide with diminished resources. Such a situation, at a time of rapid change in world conditions, demands the careful thought of those responsible for the selection of the fields and methods of work which promise to yield the most tangible and lasting benefits. These have been the preoccupying considerations for the trustees and executive officers of The Rockefeller Foundation during the past year.

"The Foundation proposes to continue its traditional work in public health, studying, through its field and laboratory staffs, diseases and the control of diseases in their environments, and giving assistance to governmental activities and to the training of personnel."

Medical Record, of January 15, 1936, editorially speaking of freedom of choice, says, "Regardless of whatever plans are proposed for the improvement of existing difficulties in medical practice, none will be adequately effective, from the viewpoint of both the patient and the doctor, unless freedom of choice is maintained. The privilege of the sick man of selecting his own medical attendant has existed from time immemorial, and it is one which he will

relinquish, if at all, with a struggle, and with a great deal of dissatisfaction and regret. The privilege of maintaining a clientele composed of what he has always called his putents, is the only one under which the doctor can give an adequate measure of efficient service.

"The number of plans proposed for the solution of the medico-economic problems of the day is legion. But the principle of freedom of choice is and should be a basic requirement when and if changes are made."

MARGARET MFAD, assistant curator of ethnology at the American Museum of Natural History, after a visit to Samor recorded her observations in an account called "Coming of Age in Samoa" This is commented on editorially in the January 15, 1936, issue of the Medical Record, as follows, "Her object was to contrast the factors and problems of adolescence in a primitive society with those in modern lands As it is not unreasonable to infer, the advantages were found to be entirely on the side of Samon If the neuroses arise from the conflicts and restraints and suppressions incident to the complicated and artificial modes of civilization, are they absent in a state of nature? Does freedom of expression and action eliminate nervous instability? Is a cramped and warped and unbiological mode of sex education and sex behavior productive of nervous and mental illnesses?

The answer is simple, using Samoa as a typical society There is an appalling lack of neuroses in Samoa There is no such state as sex-ignorance Familiarity with sex is part and parcel of education along all other lines as a natural process of growing up The older teach the younger There is the recognition of a need of a technic for the dealing with sex as an art, with the consequence that there are no neurotic pictures, no frigidity, no impotence, no false prudery, no undue stress on infidelity, no concern over illegitimacy or premarital relations There are, of course, certain standards certain tabus, certain matters of good taste and conduct But the morals are guided by one important principle, biological and sociological sound-Onanism is made nothing of, homosexuality is but a passing phase, manners is one of the determinants in promiscuity, and a sense of guilt is hardly an issue Sex expression is relatively and sufficiently, though not exclusively free, and with the acceptance of a wider range of the normal, conflicts are at a minimum Suppression seems to be the price of civilization, with the neuroses as the main by-product"

THE EDITORS OF Today, January 18, 1936, say, "Those who watch the housing situation

are becoming deeply concerned over the shortage of dwelling quarters. Vacancies, which were 8 per cent at the depth of the dupression, have sunk to 3 per cent. Since more thin 3 per cent of the dwellings in any American city are unfit for occupancy, it follows that we have a situation in which it is impossible to undouble the families that are living together, to provide new homes for new families or to ofter any choice of homes at all. In plant language, this means the landlord has the whip hand and will begin to use it as soon as he can And the end of that is rent roots, rent laws and general discontent."

DEMANDING PAY FOR DOCTORS WORKING IN clinics and dispensaries, the Bronz County Society Bulletin for January, says, "The Bronx County Medical Society (through its Committee on Clinic Physicians) is calling a mass meeting of all dispensary doctors This represents the first in the county step in the Committee's program of carrying out the resolution unanimously adopted by the Society at its June meeting purpose of the organization is to improve the clinics for the patients and to secure pay for the doctors who treat them There can, of course, be no objection to the eradication of clinic abuses Indigent patients (and no others) are entitled to the best treatment in the clinics that modern medi-cine can offer Their rights to courteous and humane attention cannot be denied there is no reason why the doctors who render the protessional services should not receive some remuneration. The burden of clinic work, unfortunately, falls almost entirely on the younger men who can least afford to give their services giatis

"Objections have been raised as to the wisdom of being on the hospital's payroll It has been claimed that the doctors will be required to punch a time clock, that only a minimum staff will be retained, and that clinic appointments will become political plums. These are minor considerations. A very strong organization will be needed to convince the city authorities that clinic physicians must be paid, and only such a strong organization can prevent the exploitation of its members. A clinic cannot exist without doctors!

"Help your County Society to help you! If you work in a clinic don't fail to attend the meeting at Elsmere Hall on Friday"

THE EDITOR OF THE Bulletin of the Central Medical Council of Brooklyn, in the January issue, speaking upon the inherent qualifications of the physician, says as follows "It is essential that the moral character of the young man aspiring to become a physician must be far above average, for

the avenues opened up to him in the practice of his chosen profession are lined with allurements and the social pressure brought to bear upon him during lean and thankless years is not inconsiderable. He must be possessed of sound judgment and able to estimate true value, for this is present in every case he undertakes to handle, and besides medicine, as it advances, is no less free from follies and fads than any other phase of life. It is necessary for him to be ingenious because occasions will arise from time to time when no text book learning will apply, but he must, through his own inventivity work out to a solution the problems that are pressing. Penknife tracheotomies and kitchen table appendectomies still exist in a hundred different forms. The young man must be versatile. Without exception, the practice of medicine takes into practical account more of every field of learning than any other occupation or profession under the sun. He must be willing and capable of shouldering responsibility. At times it may be necessary to be bold, strong enough to face the unknown, stout enough to withstand whirlwind disaster of a suddenness greater than that of torna-If surgery is in his does or lightning. realm he must constrain himself to honestly opine to do so notwithstanding persuasive opinions and tactics of others and strike freely when that is the action of choice. He must be a good sportsman, cooly cal-culating his odds and the stakes for which he plays. It may be necessary to take chances when the situation demands and be unafraid. His command of speech must be extraordinary, for people in distress cling to the words of the physician. He must know when to talk and when to remain silent. Other qualities that may be mentioned are those of patience and persuasion, for he must make others share that patience with him. He must be undisturbed with little set-backs that occur along the course of every critical illness and must never be the subject of panic. Frequently, in the course of a physician's career, he will meet those who are ungrateful. To this ungratefulness he must be insensible. He must be forgiving and charitable. The patient whom he has served faithfully and who repays his labors with insult and then later returns in distress and demands his services, he must meet kindly without vindictiveness. Lastly, this trend of thought brings to mind the words of one of our physicians at the hospital who preaches that the physician must be as a father—understanding, guiding, advising, admonishing, gentle but stern when the occasion demands and ever with the interest of his fellowman at heart in a measure at least commensurate with his own.

"A superman—yes—that is what the patient asks of him and it seems that, in times like these, that is what the world expects."

CHARLES G. DAWES, former Vice-President of the United States, in a statement published by the Saint Louis Medical Society Bulletin, Volume III, Number 1, says as follows, "If you work in a profession, in Heaven's name work for it. If you live by a profession, live for it. Help advance your co-worker. Respect the great power that protects you, that surrounds you with the advantages of organization, and that makes it possible for you to achieve results. Speak well for it. Stand for it. Stand for its professional supremacy. you must obstruct or decry those who strive to help, why-quit the profession. long as you are a part of a profession, do not belittle it. If you do you are loosening the tendrils that hold you to it, and with the first high wind that comes along you will be uprooted and blown away and probably you will never know why." The Bulletin suggests that this be adopted as our motto.

"The quality of medical service which is one of the outstanding features of American medicine, must be maintained. Every medical society is the natural guardian of the quality of medical service given in its locality. If this quality deteriorates, the battle is lost no matter how widely that service is spread or whatever may be the method or the amount of payment." Thus does R. G. Leland, M.D., of the A. M. A. express himself in the January issue of the Westchester Medical Bulletin.

ON JANUARY 8, the annual report of the United States Public Health Service was made public. "Among the facts recorded in the report were:

The 1934 death rate of 10.9 per 1,000 population was lower than any recorded

earlier than 1932.

The 1934 birth rate broke the downward trend of thirty years.

The 1934 infant mortality rate was lower than any before 1932.

During 1934, there were no cases of cholera or yellow fever and only one death from the dreaded plague.

Studies of the effect of the depression showed 'no striking differences' in children's weight but general increased sickness among the 'depression poor.'

Dr. Cumming said that the 1934 death rate of 10.9 was slightly higher than the record low of 10.5 in 1933.

Doctors generally agree that the depression may have had little influence on the

slight rise in the 1934 death rate. They pointed out that with the lengthening of the normal expectancy of life the death rate would go below 'normal' while this stretching out was taking place. Then the death rate would increase slightly and remain fairly constant

The 1934 birth rate was three per cent higher than in 1933, the report showed. That meant that 94,000 more babies were born in the nation in 1934 than in 1933. The trend for births has been downward for

more than three decades.

In 1934, 599 out of every 1,000 babies born died during the first year of their lives. The previous year 582 died. The 1934 rate was lower than any year earlier than 1932." The foregoing is from the New York Herald Tribune of January 9, 1936.

Dr. Grorge R. Harris of Pittsburgh, Pennsylvana, under date of January 13, 1936, writing in *The New York Funes* of January 17, 1936, says, ". When health insurance is characterized by Dr. Kingsbury as the Cinderella of the security bills, is not that comparison a little unfortunate? If memory serves, Cinderella's family was a rather scurvy lot. Does he imply that the other social security bills are comparable to the greedy, selfish sisters? Possibly he is correct.

"Dr. Gray attempts to pour oil on the troubled waters by stating that 'we do not want to revise fees, or add to expenditures'. Dr. Gray drew up the Model Health Bill, and he should know that in Pennsylvania the enactment and application of his bill would have added approximately \$90,000,000, yearly to the costs of running the State Is \$90,000,000 for one year no addition to

expenditures?

"There is nothing to clear up, so far as the medical profession is concerned, about health insurance, nor have we been under any misapprehension regarding the motives behind this unwarranted and unwanted interference with the rights and duties of a profession with a long and honorable record of service to humanity. But the public should be informed that for every doctor in a health insurance plan there is always one lay position, sometimes more.

"With the health record, the morbidity record and the overburdening cost against health insurance plans, it is high time that the motives behind the efforts to force such plan upon the citizens be brought out. Can it be that jobs under such a scheme would influence professional agitators to create

a demand for a supply?

"It is too bad that Mr Epstein and Dr. Kingsbury descend to such charges and muendo in what should be calm and dispassionate discussion of the sickness insurance question. The medical profession is well content to stand on its record of service, with and without pay. It ill becomes a profession such is that of social service—if it can be called a profession, after less than thirty years of existence—to prate of service when that so-called service has always been fully recompensed."

FROM THE EDITORS OF Today, in the issue of January 11, 1936, we find the following: "Man cannot plan even his own individual actions for a day ahead, says Dr. P. A. Sorokin of Harvard, when he does, he invariably discovers that he has failed by about twenty per cent to accomplish what he set out to do From this, the eminent sociologist argues that it is futile to plan for the future of society Well, another sage once remarked that if at the end of a day a man discovered that he had accomplished all he set out to do, it merely proved that he did not set out to do enough the copybooks used to put it, with Spencerian flourishes, 'Not failure, but low aim, is crime'"

THE DOCTOR AND THE FACTORY

Study of amendments to proposed rules and regulations to govern medical bureaus in industrial plants servicing workmen's compensation cases is now being made by a joint committee of industrial and labor representatives and members of the State Medical Society. Under the Workmen's Compensation Law as amended by the last Legislature medical bureaus may no longer be operated in compensation cases by insurance carriers, and medical bureaus in industrial plants must meet the approval

of the medical societies of the counties in which they operate before they may be licensed by the Industrial Commissioner

At a recent hearing in New York city on these rules the question finally resolved itself into whether a physician must be in constant personal attendance at such a bureau or could give personal supervision and be available at all times. This is the principal question which the joint committee of industrial and labor representatives and physicians is now considering.

PROCLAMATION

STATE OF NEW YORK EXECUTIVE CHAMBER ALBANY

As the late winter season approaches each year, the peak of pneumonia is reached in this State. The State Department of Health, working with the Medical Society of the State of New York, the State Association of Public Health Laboratories, the Metropolitan Life Insurance Company and the Commonwealth Fund, has inaugurated a united effort which will have as its objective the saving of 3000 lives each year from pneumonia.

The public must be informed that early recognition and medical handling of pneumonia cases is just as much an emergency as acute appendicitis or diphtheria, and that proper nursing care is essential. Many neglected colds develop into pneumonia. If the disease occurs, science has provided serums for certain types of pneumonia which aid nature in a cure. I have recommended to the Legislature an additional appropriation for the purpose of making such serum available to the people of the State. Science, however, is helpless unless the people themselves cooperate fully in using the knowledge which science has made available.

I am convinced that the organized forces of medicine and public health can call to their assistance civic bodies, welfare agencies, industrial and labor groups, the schools, churches, newspapers and radio stations to lead the public as a whole to a better understanding that many cases of pneumonia can be prevented and that many lives can be saved from this cause.

THEREFORE, I, Herbert H. Lehman, Governor of the State of New York, do hereby proclaim the period from January 15 to February 15, 1936, as a season for all citizens to join in a common effort to reduce the number of pneumonia cases and deaths, by disseminating knowledge of prevention through simple health rules and by prompt action in securing diagnosis and treatment where pneumonia is suspected, and I do hereby urge the people of the State in their several capacities to join wholeheartedly in this important endeavor.

(L. S.)

GIVEN under my hand and the Privy Seal of the State at the Capitol in the City of Albany this fifteenth day of January in the year of our Lord one thousand nine hundred and thirty-six.

BY THE GOVERNOR:

(Signed) HERBERT H. LEHMAN

(Signed) Walter T. Brown Secretary to the Governor

667 Madison Avenue, New York City

To the Editor:

In your editorial "Nonspecific Colitis" in the issue of December 15th you state in part "Continued investigation into the history of patients suffering from a colitis of undetermined original together with extensive tests to determine the presence of sensitization will add further to our knowl-

edge of this subject."

I am taking the liberty of enclosing a reprint showing that a great amount of work has already been done and that in my humble opinion nonspecific ulcerative colitis is directly due to bacillary dysentery. The follow-up studies of the Jersey City epidemic show that 10.7 per cent developed chronic ulcerative colitis at the end of 9 to 12 months. This figure includes only cases proven by roentgenographic studies sigmoidoscopy.

Faithfully yours,

Joseph Felsen, M.D.

December 20, 1935

[The reprint was of an article written by Dr. Felsen which was published in this Journal June 1, 1935, p. 576—Ed.]

313 East 86th Street New York City

To the Editor:

Reading your article "Germany Today in International Science Meetings" (January 15, p. 122), I feel inclined to ask you why you with the others pick out only Germany as your target. I personally don't like what you call goosestepping in art and science, and rather give up my work than submit to an unwanted dictation. I think whenever we want to fight for the precious gift of freedom of science we should look upon Russia and Italy as the greatest offender. Both countries are inviting scientific meetings and many scientists of international fame have been attending meetings both in Moscow and Rome. In spite of the fact that Russian scientists of the old regime have suffered a fate so terrible that it is without parallel in history, we have not heard of anybody suggesting recently to isolate Russian scientists who willingly submit to the bolshevistic doctrine.

But why go so far? Recently we could

read about the indictment of a whole university in the United States located in one of the centers of industry. The evidence brought out and published in our papers proves that a dictatorship is in existence there exercised by a group of bankers and industrial magnates. It seems that it effectively strangles free thought and independence in scientific research much more than a national dictator can ever hope to accomplish. At least in a country like Germany the dictatorship has been brought about by a large majority vote of the whole population and if they grieve about it today in certain quarters they are only to blame themselves, but in our particular case right here in the United States, there are only a handful of so-called powerful men, who dictate to every professor, what he is supposed to say or to discover. If I would have to choose between the two I would prefer a national dictatorship and try to live under the illusion that it is wartime, when even in the most liberal country everything is subordinated by force to only one aim. Don't we have enough experience in this matter?

After all, it seems that only a man financially and politically independent, who is able to support himself and his work out of his own material means, can call himself free. But where in the world is this man to be found? Maybe we are incorrect in thinking of individual freedom in all human endeavors, maybe we have to get used to a more collectivistic nomenclature. We should have learned by now that everything is

"relative" in life.

Very truly yours, EDMUND F. KOHL, M.D.

January 19, 1936

[Note:—Our correspondent missed the point of our editorial entirely. We are here concerned not with the action of Germany toward her own men of science, or what she does or does not do to them. We are very much interested and protest the machinery set up to utilize international scientific gatherings for Nazi purposes. Neither Russia nor Italy ever did this. We are not concerned with dictatorship per se. Finally, at this time, we are unconcerned as to local suppression of free scientific expression. We object to measures designed to control international congresses which may meet in Germany.—Editor.]

Society Activities

Committee on Workmen's Compensation

COMMUNICATION No. 12

The Subordination of Fees. The amended Workmen's Compensation Law directs that the Industrial Commissioner shall remove from the list of approved physicians one who "has participated in the division, transference, assignment, rebating, splitting or refunding of a fee for medical care under this chapter."

Some hospital superintendents are making suggestion to their staff physicians that after the physician has rendered his bill and receives the check that he immediately make it payable to the hospital for some institutional project or for the use of the staff generally.

May we remind physicians of New York State that this constitutes "subordination of fee" and lays the physician liable to removal from the list of approved physicians.

Some hospital superintendents are proposing that the hospital act as agent for the pathologist and roentgenologist and for other physicians of the staff organization for the purpose of rendering of bills under the Workmen's Compensation Law. As we understand the law, "agency" is only provided for a deceased physician when his affairs are in the hands of an executor or other "agent" of the estate. The bill for professional service must be made in the name of the physician rendering the service and must be paid to him. We are aware that some hospitals are violating the Law in this respect. It may be necessary to cite these violations of the Law to the Attorney General for legal action, if such violations are continued.

Perhaps some violations of the Law are escaping our notice. Any information mailed to this Committee or to any member thereof will be held confidential insofar as its source is concerned. It is our purpose to protect the profession against further exploitation. The Law is clear, it is up to each individual physician to cooperate in its enforcement.

Charles Gordon Heyd, M.D., *Chairman*. David J. Kaliski, M.D. Frederic E. Elliott, M.D.

Rules and Regulations Promulgated by the Industrial Commissioner Covering Chapters 258 and 930 of the Workmen's Compensation Law

1. All doctors whose applications have been disapproved by the various County Medical Societies may continue to treat workmen's compensation cases until a final decision is rendered by the Industrial Council.

2. All reports, except Form C-104, filed by attending physicians and specialists should be verified before a Notary Public or a Commissioner of Deeds, to insure their value as prima facie evidence in a compensation case.

3. In the event of a serious accident requiring immediate emergency medical aid, an ambulance or any physician may be called

to give first aid treatment.

4. Homeopathic and osteopathic societies and boards should receive applications from homeopaths and osteopaths only and recommend for authorization to treat workmen's compensation cases only homeopaths and osteopaths.

5. All specialists, consultants, etc., shall submit a report of their findings in triplicate; one copy to the Industrial Commissioner, one to the attending physician, and one copy to the employer or insurance carrier. If the specialist acts as attending physician, he should file a forty-eight-hour

report with the employer or carrier and with the Industrial Commissioner.

6. A registered physiotherapist may treat workmen's compensation cases at his own office or bureau when the case is referred to him by an authorized physician. The authorized physician should, however, give written directions to the physiotherapist as to the kind of treatment to be rendered and the number of treatments to be given. These directions must be given in writing by the physician and shall constitute a part of the record of the case.

7. Removal of physicians from panels. Section 13-D. (a) The doctor accused of misconduct shall be notified of the charges in writing by the Medical Society or Board that recommended him. He shall also be notified as to the date and time of the hearing. (b) Careful records shall be kept of the minutes of the hearing. (c) These records, together with the report of the Board of the Medical Society or other Board, with its findings, shall be submitted to the Commissioner.

Appeal by physicians to the Industrial Council to be referred to a Sub-Committee to report findings to Council. (a) The doctor appealing and the Medical Society or

other Board shall be notified in writing as to the date of the hearing (b) The doctor may be represented by counsel (c) Accurate stenographic or stenotype minutes of the hearing shall be kept for the files of the Commissioner and Industrial Council (d) Findings of the Committee shall be submitted to the Industrial Council for final action

8 Arbitration of Medical Bills -A panel of physicians is to be appointed by the Presi dent of each County Medical Society, who shall submit the names of the physicians on the panel to the Industrial Commissioner The Commissioner shall, when arranging hearings on medical bills, select two members of each Arbitration Committee from this panel, and two physicians are to be selected by the employer or insurance carrier from the membership of the Medical Society of the State of New York, qualified under this Act, for each arbitration session, the Industrial Commissioner to set the dates for all hearings and notify all interested parties The Arbitration Committee shall submit to the Industrial Commissioner its decisions on a form prescribed and provided by the Industrial Commissioner, who will then for ward notice of decision to all interested parties. If the physician whose bills are be ing arbitrated is a member in good standing and duly qualified by the New York Osteo pathic Society or the New York Homeopathic Society, the members of such Arbitration Committee are to be appointed similarly and shall consist of physicians of such organizations, the president of such organizations to make the designation pro uded herein

In the event of disagreement as to the value of medical services rendered a hear ing shall be held in the county in which the doctor practices or in which his main or principal office is located Notice of this hearing shall be sent to the doctor or hos pital who rendered the services the employer and the insurance carrier, any of whom may appear or be represented, if they so desire The Arbitration Board shall pass upon the matter in dispute in accordance with Section 13 G of the amended law

Careful records of the hearing shall be kept in the office of the County Medical

Society

In the event of disagreement as to the value of medical services rendered by members of the New York Osteopathic Society a hearing shall be held at a location convenient to the interested parties. The Industrial Commissioner is to select two members from the panel of physicians appointed by the President of the New York Osteopathic Society, for each arbitration session, and the employer or his insurance carrier is to

select two arbitrators from the membership of the New York Osteopathic Society who have been duly qualified under this Act

The Arbitration Committee shall pass upon the matter in dispute in accordance with Section 13 G of the amended law

Careful records of the hearing shall be kept in the office of the New York Osteo

pathic Society

9 In the event of rejection of a physician by a County Medical Society or other Board, the jurisdiction of the County Medical Society or other Board has terminated and it cannot reconsider its action Each County Medical Society or other Board must pass upon the application of each physician within thirty days of the receipt of the application and notify the Industrial Commissioner of its action

10 Bills for x rays and consultations shall be submitted for payment directly to the employer or carrier by the specialist render-

ing the service

11 A hospital may not secure a license to operate a medical bureau to render care to

compensation cases

12 No insurance company or self insurer may reduce the size of notice to employees (Torm C 105), which is to be placed in all places of employment covered by the Act, unless such permission is granted on application to the Industrial Commissioner

13 Physicians treating claimants in hospitals may secure the signature of claimant for authorization to obtain copies of any

necessary hospital records

14 The physician in attendance in public hospitals must be the judge as to when the "emergency status" of the case has terminated In case of a dispute the matter shall be referred to the Compensation Board of the Medical Society of the County in which the hospital is located, for immediate decision

15 Medical inspectors of insurance companies shall be admitted to hospitals or other institutions where injured employees are confined upon proper identification, for the purpose of complying with Section 13-7

16 No license is necessary to operate a first aid station for emergency treatments, but no subsequent treatments are to be rendered by anyone other than a qualified physician

17 The physician in attendance must seek authorization for a specialist first from the employer or carrier. If unable to secure it he may apply to the Industrial Commissioner in accordance with Section 13 A 5

18 The authority of an employer for the services of a specialist in excess of a \$2500 fee, applies only to the necessity for such services, but the choice of such specialist is

entirely within the jurisdiction of the injured worker.

19. All medical bureaus and laboratories in operation on July 1, 1935, shall be charged a license fee, effective July 1, 1935, to and

including June 30, 1936. 20. When it is in the

20. When it is in the interest of the injured employee, and where an x-ray is required and it is impossible to secure the services of a qualified x-ray specialist, the Board of the local County Medical Society may designate a specially qualified individual to take x-ray pictures under the supervision of the attending physician. The attending physician, however, shall render a bill for such service to the employer. This in no way, however, deprives the employer or insurance carrier from having other x-ray pictures taken if they so desire.

21. No advertising matter of any nature, on compensation work, by authorized physicians, medical bureaus, or laboratories, will

be permitted.

22. All County Medical Societies and other Boards shall be instructed to first investigate all complaints submitted to them, and if the evidence warrants it, charges shall be preferred against the physicians, after which the physicians shall be notified in writing of the charges, as well as given a bill of particulars, so that they may be in a position to defend themselves properly at the hearings.

23. Physicians authorized to treat workmen's compensation cases, when requested to supersede another physician must, before beginning treatment of such patient, make reasonable effort to communicate with the attending physician to ascertain the patient's condition. The superseding physician must also advise the attending physician of the name of the person who has requested him to assume care of the case and state the reason therefor. If the second physician cannot contact the attending physician, and the claimant's condition requires immediate treatment, the said physician should advise the doctor previously in attendance, with forty-eight hours, that he now has the patient in his care.

24. Hospitals shall render bills for board and room accommodation, medical and surgical supplies, nursing facilities, and routine laboratory service. Bills for all services rendered by physicians in hospitals, including physiotherapy, x-ray, pathology, anesthesia, medical and surgical care, etc., shall be made out separately and paid directly to the doctor rendering the service.

25. All medical reports filed by attending physicians and specialists must contain the authorization certificate number and code

letters.

ELMER F. ANDREWS Industrial Commissioner

January 3, 1936

Committee on the Study of Tuberculosis and Workmen's Compensation

A PROGRESS REPORT

I. Introduction: In the Spring of 1934 Dr. James Alexander Miller, for many years president of the New York Tuberculosis and Health Association, made the suggestion that, after long experience with tuberculosis cases, he thought it most important that a study should be set up as a result of which it might be possible to prepare standards for the determination of causal relationship and tuberculosis. Dr. Miller indicated that, among other things, great doubt existed as to the effect of accidents in the aggravation of an old tuberculous lesion; and also as to the time element involved in any such aggravation. In other words, was it necessary for active symptoms to develop a day, a week, a month or six months after the accident? These are extremely important matters from a medicolegal point of view, and it was Dr. Miller's thought that a properly organized study should lead to the formulation of a definite standard in the determination of causal relationship.

II. Preliminary Study: Following this suggestion, a small committee was organized

to arrange for a preliminary investigation on the basis of which the larger study could be made. An appeal was made to the New York Tuberculosis and Health Association to undertake this task. As a result, a careful analysis was made over a period of months of a fairly large number of closed cases in the death file of the Department of Labor. All these cases involved claims for compensation on the basis of pre-existing tuberculosis. The complete files were read, the pertinent data tabulated, and much interesting information was made available.

III. Organization of the Committee: As a result of this preliminary investigation and analysis of closed files, the full Committee on the Study of Tuberculosis and Workmen's Compensation was organized under the chairmanship of Dr. James Alex. Miller, including Drs. Edward P. Eglee; Roscoe N. Gray, Surgical Director of the Aetna Life Insurance Company; Oswald R. Jones; Adrian Van S. Lambert; Raphael Lewy, Medical Director of the Department of Labor; Edward Nash, Medical Director of the State Insurance Fund; Max Tasch-

man; Mr. Verne A. Zimmer, Director of the Division of Workmen's Compensation of the Department of Labor; and Dr. Jacob A. Goldberg, Secretary, Full cooperation was pledged by the New York Tuberculosis and Health Association, National Bureau of Casualty and Surety Underwriters, National Council on Compensation Insurance and, above all, by the New York State Department of Labor. The study was immediately set afoot and the first examinations were made in lune 1934.

IV. Objects of the Study: The objects of this study in the main were (a) to determine criteria of causal relationship between industrial accidents and conditions to pulmonary tuberculosis: (b) to determine criteria of disability from such tuberculosis, including criteria of total and partial disability and the duration of the disability; (c) to determine criteria of activity of the disease; (d) incidentally, the study will include criteria for the diagnosis of the presence of pulmonary tuberculosis. These objects have been borne in mind in the work of the Committee, and an analysis of the situation based upon the experience, is being made in order to furnish a basis for further progress during the coming year in the determination of the final criteria which may be determined.

V. Methods Pursued: After the organization of the Committee, the machinery was set going. Arrangements were made for all cases referred by the Department of Labor to be examined at an impartial place in the midtown area of the city, i.e., at the Bellevue-Yorkville Health Center, 325 East 38th Street, New York City. The procedures followed in the examinations are herewith detailed:—Cases from the Department of Labor, in which there is a question of casual relationship and tuberculosis, are sent to the Secretary. He then has the files carefully studied, pertinent data copied out, all medical records completely transcribed, medical testimony and other pertinent testimony likewise transcribed, and pre-pared for the permanent files of the Committee. The claimant is then requested to come for preliminary examination. This includes the taking of a chest x-ray, the collection of sputum for concentrated analysis, the taking of a complete industrial history, a history of previous illnesses, history of present complaints, history of accident and injury in detail; temperature, pulse, respiration and weight are also recorded; and certain other data are set down in an especially prepared form. The applicant is then told to return within a few days when the results of the x-ray are available and the sputum has been examined. At this second appointment a committee of three impartial tuber-culosis specialists, who serve as the experts, are prepared to examine the applicant. This committee is a special panel appointed by the State Industrial Commissioner, and consists of Drs. James Alex. Miller, J. Burns Amberson, Jr., Edward P. Eglee, Grant Thorburn, Max Taschman, and Oswald R. Iones.

The patient goes to the first specialist to whom is given the complete transcribed file, the x-ray taken at the previous appointment, all x-rays which have been obtained through cooperation of the Department of Labor or the carrier, and all data obtained from the patient. A careful examination is then made of the claimant and the information is recorded by the examiner. He is then examined a second time and independently by another member of the panel who goes through the same procedure, without having available the report of the first examiner; thereafter he goes to a third examiner who goes through the same process. After he is independently and completely examined by the three medical experts, the three physicians discuss the case among themselves and decide on the opinion. In order to facilitate matters, one member of the Committee serves as chairman and signs, in affidavit form, the final report which goes to the Department of Labor; the names of the other two physicians are entered on the record as concurring in the report.

The question has arisen as to what is done in case one of the Committee does not agree with the other two. This has happened in only one case so far. In such case, a second panel of three imparital experts, also appointed by the Industrial Commissioner, is called in and the claimant is completely re-examined on the basis as outlined. The second panel agreed unanimously with the majority opinion of the first panel. This is the current procedure.

VI. Financial Arrangements: The plan pursued in financing this study was agreed upon after consultation with the Industrial Commissioner and with representatives of both mutual and stock insurance companies. It was suggested to the carriers particularly that it would be necessary to have a minimum fee of \$50 per case in order to cover the cost of the work of the Committee. There was strenuous objection on the part of some of the representatives of the carriers to this figure and a compromise was finally affected whereby a fee of \$40 was to be paid until some experience had been had with this fee arrangement. This plan was in effect for approximately one year, after which it was found necessary to have this fee increased to \$50. The original fee of \$40 would have been adequate if a large enough number of cases had been sent for examination by the Committee.

Arrangements are made for the examination of three claimants at each clinic session. The fee received covers compensation to each of the three examining physicians who receives \$25 for serving as an examiner of three claimants in an afternoon, the cost of x-ray services, laboratory service, secretarial, stenographic, messenger service, supplies and equipment, transportation, printing, postage, and other incidentals. The Treasurer of the New York Tuberculosis and Health Association serves as Treasurer of the Committee, and all checks received from the carriers are turned over to the Treasurer of the Association, who keeps a separate account for the purposes of the Committee.

The standard fee paid to the medical examiner for testifying at a hearing in the Department of Labor was fixed by agreement at \$25. Bills for such amounts are forwarded to the carriers or claimants' representatives through the Division of Workmen's Compensatios, Department of Labor.

Since the inception of the Committee's work, the impartial medical experts have been called upon to testify in a relatively few cases.

VII. Results Thus Far Achieved: It was originally intended that a total of 500 cases would be examined within a period of one year or thereabouts, and that these cases would be studied and followed up within the second year. Due primarily to the lack of employment in the heavy industries in New York City and State, a comparatively small number of cases have been referred to the Committee. To date a total of ninetyseven claimants have thus far been referred for examination. It is too early to speak of results except to indicate that the work of the Committee has elicited the interest and hearty cooperation of the carriers, the claimants and the representatives of the Department of Labor.

The results of the first year's study are now being analyzed from the standpoint of the four primary objects of the study, but the data available are still insufficient on which to base any conclusions. These will not be reported upon until the study as a whole has been concluded.

VIII. Termination of the Study: In the discussions preliminary to the formal undertaking of the study, the Committee was led to believe that a total of 500 cases would probably be referred for study within one year after examinations were started. The

Committee thereupon assumed that the medical examinations would be completed within one year and that phase of the study terminated at that time. However, as already indicated, the marked and continued depression in the building and other heavy trades and industries naturally brought with it a marked decrease in the number of industrial accidents, particularly those in which the Committee was interested.

The Committee has decided that a special study of this kind by a small group should be definitely limited in time, and consequently it is planned to discontinue medical examinations after December 31, 1936, and to base the formulation of standards and the final report on the total number of cases already examined and those to be referred and examined during the year 1936.

When the final report of the Committee is presented, it is hoped that we may have agreed upon other definite standards upon which to base the criteria originally determined as the main objects of this study. In addition to this, it is hoped that the type of organization which has been in operation in making this study may assist in the more successful operation of a special panel of specialists to be selected and operated under the provisions of the revised Workmen's Compensation Act, and that consequently it may be of definite assistane to the Industrial Commissioner and also to the representatives of the county medical societies who are charged with the responsibility of selecting those specialists.

IX. Summary of Financial Statement: The following is a summary of the funds received and expended, as prepared by the Accountancy Division of the New York Tuberculosis and Health Association:

Receipts (June 1, 1934, to November 30, 1935): Total collections from Insurance Com-

panies

Dishursements (June 1, 1934 to November 30, 1935): Physicians, for services rend-\$2,125.00 1,315.00 308.32 89.30 125.49 37.00

Total Disbursements to November 30, 1935

4,018.46

Excess of Receipts over Disbursements ...

\$6.54

In addition to these contributions made through the insurance companies, the New York Tuberculosis and Health Association has contributed up to the present time, through the services of its staff and organization, equivalent to \$2,500 for which it has not been reimbursed.

Committee on Legislation

Bulletin No. 1

January 8, 1936

The 1936 Legislature has started its work in a very businesslike way. Both houses are organized and have received bills and already there are quite a number introduced in which we shall have a very definite interest. We shall report in our bulletins all of the bills that have any direct bearing on the practice of medicine or public health and some others that may have an indirect bearing on these subjects or the welfare of the physician, as, for instance, amendments to the Welfare Law, the County Government Law, Tax Law, etc. To date the following bills have been entered upon the docket:

Senate Int. 12-Buckley; Assembly Int. 30-E. F. Moran; to amend the Judiciary Law by providing jury duty exemption only for lawyers, doctors, clergymen, firemen, policemen, U. S. Soldiers and sailors and ship's officers. Referred to the Judiciary

Committee.

Comment: This bill is identical with the one we considered last year, introduced by Senator Buckley. It exempts physicians who have patients requiring daily attention.

Senate Int. 17-Fearon; Assembly Int. 51-Parsons; County Law, for optional forms of county government to be known as the elective county executive form, appointive county executive form with full administrative powers, appointive county executive form with restrictive powers, board of district supervisors form and board of supervisors form. Referred to the Internal Affairs Committee.

Senate Int. 20-Desmond, County Law, for optional forms of county government to be known as county mayor, county manager, county director, and county board forms. Referred to the Internal Affairs Committee.

Comment: Two forms of suggestive

county governments.

Senate Int. 43-Feinberg, to amend the Correction Law so as to limit hours of guards and other uniformed employees in state prisons, state reformatories and hospitals for criminal insane to 48 hours for six days, at least one day a week to be a day of rest. Referred to Penal Institutions Committee.

Comment: A bill of this character was passed by both houses last year but was vetoed by the Governor. Without doubt other bills similar in character will be introduced this year with an attempt to have one of them enacted.

Senate Int. 50-Pitcher; Assembly Int.

41-Brownell, creating a temporary state commission to make a comprehensive study and analysis of unemployment and employment relief and laws relating thereto, and appropriating \$50,000. Referred to the Finance Committee.

Comment: Reporting this bill is also in-We know you will be interested in the attempts that will be made this year to incorporate the TERA and other charity activities into a more permanent There are suggestions that all program. of this work should be referred directly to the Department of Social Welfare.

Senate Int. 51-Pitcher; Assembly Int. 45-Gamble; to amend the Constitution by providing for a four-year term for Sena-tors and two-year term for Assemblymen, and for referring proposed constitutional amendments to the legislature whose assembly shall have been chosen at next general election of Assemblymen instead of Senators. Referred to the Judiciary Committee.

Comment: Purely informational. Senate Int. 54-Stagg; Assembly Int. 47-Messer; amends the Vehicle and Traffic Law by providing for a flat registration fee of \$3.00 for motor vehicles. Referred to the Motor Transportation Com-

Comment: Purely informational. Senate Int. 57—Wicks; Assembly Int. 61-Wadsworth, amends the State Charities Law, repeals Chapter 798 of the Laws of 1931, by abolishing the Temporary Emergency Relief Administration assigning its powers and duties to the Social Welfare Department. Referred to the Relief and Welfare Committee.

Senate Int. 62-Williamson, amends the Surrogate's Court Act by providing debts of a decedent shall be second in order of payment by an executor and administrator, due for hospital, physicians', surgeons', and nurses' services rendered to decedent during last illness. Referred to the Judiciary Committee.

Comment: This bill was before both houses last year but was killed in committee in each house. We approved the

bill and gave it our support.

Senate Int. 71-Williamson, adds new section to the Tax Law imposing an emergency filing fee or tax of \$4.00 on gross personal incomes of \$1,000 or more for year 1936, 50 per cent of moneys to be paid to state for unemployment relief and such proportion of remaining 50 per cent to each county treasurer as population within towns and cities of county bears to aggregate population within all towns and cities of the state. Referred to the Taxation Committee.

Comment: Purely informational. Senate Int. 104—Feld, adds new Article 17-b to the Public Health Law by providing no bread to be sold in loaf form, whole or sliced, shall be transported, handled or sold unless securely wrapped in wax, cellophane or other wrapping of equal texture and security, violation being made a misdemeanor. Referred to the Health Committee.

Senate Int. 134—Desmond, amends the Civil Practice Act by eliminating from section 354 provisions relative to testimony of physicians, surgeons, and nurses, and embodying them in a new section. Referred to the Codes Committee.

Comment: By this amendment Senator Desmond proposes to take certain matter from Section 354 of the Civil Practice Act, which relates to "evidence" given, and place it as 296-a in the section devoted to "depositions." He is removing nothing from the law and in no way at all changing the law with regard to confidential communications. It appears to be an effort to clarify the law by placing this clause in the section to which it properly belongs.

Senate Int. 135—Nunan; Assembly Int. 115—Fitzpatrick; Labor Law, providing no state hospital nurse or other employee shall be allowed to work more than eight hours a day and eight consecutive hours in any twenty-four shall constitute a legal day's Referred to the Labor Committee.

Assembly Int. 1—Whitney, appropriates \$2,000,000 to pay indemnities for bovine animals killed on account of infectious or communicable diseases, other than tuber-culosis, but including Bang's abortion disease and mastitis. Referred to the Ways and Means Committee.

Assembly Int. 39—Bartholomew, appropriates \$1,000,000 to pay indemnities for bovine animals killed on account of disease known as mastitis. Referred to Ways and Means Committee.

Assembly Int. No. 40-Bartholomew, appropriates \$1,000,000 for payment of indemnities for bovine animals killed on account of Bang's abortion disease. ferred to the Ways and Means Committee.

Assembly Int. 84—Dunn, creates a temporary commission of seven members to be appointed by Governor to make a comprehensive study and analysis of Bang's abortion disease and mastitis of cattle and appropriating \$25,000. Referred to the Ways and Means Committee.

Comment: Endeavors were made last year to have the state take the same interest in eradicating animals affected with Bang's disease as has been taken in freeing herds of tuberculosis. One of the probable reasons why those endeavors did not ma-

terialize was the lack of information as to the prevalence of this disease among ani-The importance of protecting man against the disease was thoroughly realized. The Governor, in his address to the Legislature, refers to the matter in the following paragraph: "I believe that before the state embarks upon a program of indemnity payment to farmers for cattle reacting to Bang's disease or mastitis, the Legislature should have before it much more data than is now available to any of us. Among the things that should be considered are: losses to the dairy industry; health factors; ultimate cost to the people of the state. you know, the campaign of tuberculin testing has, over a period of 17 years, cost the state more than \$50,000,000, apart from the losses incurred by the dairy farmer himself. Therefore, in order to explore these various important considerations, I recommend that your Honorable Bodies establish a commission of experts which will study the subject and submit its report to the Legislature.

Assembly Int. 83-Doyle, adds new section 4-a, Public Health Law, prohibiting experiments upon living dogs, violation being made a misdemeanor. Referred to the Health Committee.

Comment: The antivivisection bill has come in early this year and one interesting observation is that its sponsor is the chairman of last year's Public Health Committee.

The personnel of the Senate committees remains the same as last year with the exception that Senator Howard, of Kings County, will head the Committee on Labor and Industry, succeeding the late Senator Naturally, all the committees in the Assembly have a new personnel this year. They will all be found in the "white book" but that will not be published for some time. In the meanwhile it may be necessary for you to communicate with members of some of the committees:

Assembly Committee on Codes. James R. Robinson, Cch., Tompkins; Harry D. Suitor, Niagara; George B. Parsons, Onondaga; Albert Haskell, Jr., Cortland; J. Maxwell Knapp, Sullivan; Harold P. Herman, Nassau; Warren O. Daniels, St. Lawrence; Harold B. Ehrlich, Erie; Russell Wright, Jefferson; Fred A. Young, Lewis; John A. Byrnes, New York; Meyer Alterman, New York; Peter T. Farrell, Queens; Crawford W. Hawkins, Kings; Irving D. Neustein, New York.

Assembly Committee on Public Education. Harry L. Averill, Chr., Wayne; Rainey S. Taylor, Orange; Wheeler Milmoe, Madison; Emerson D. Fite, Dutchess; William E. Morris, Saratoga; Frank G. Miller, Tioga; Warren O. Daniels, St. Lawrence; Jane H. Todd, Westchester; Chauncey B. Hammond, Chemung; McKenzie B. Stewart, Clinton; Floyd E. Mecks, Schuyler; James L. Dixon, Queens; Patrick H. Sullivan, New York; F. J. McCaffrey, Jr., New York; George Kaminsky, Kings.

Assembly Committee on Public Health. E. O'den Bush, Chr., Delaware; James D. Burgdorf, Cayuga; Edward F. Vincent, Broome; Ernest J. Lonis, Oswego; Jane H. Todd, Westchester; Warren O. Daniels, St. Lawrence; Thomas A. Leahy, Essex; Frank A. Gugino, Erie; Edward P. Doyle, Kings; Edwin L. Kantowski, Erie; Aaron F. Goldstein, Kings; S. A. Farenga, New York; James V. Mangano, Kings; Charles Bormann, Richmond.

Assembly Committee on Labor and Industries, Wilson Messer, Chr., Steuben; Frederick A. Washburn, Columbia; Herbert A. Rapp, Genesee; Harold C. Osterag, Wyoming; Fred S. Hollowell, Yates; James E. Hill, Broome; Floyd E. Meeks, Schuyler; William R. Williams, Oneida; Fred A. Young, Lewis; Thomas A. Leahy, Essex; Anthony J. Canney, Erie; Leonard Farbstein, New York; Charles H. Breitbart, Kings; F. J. McCaffrey, Jr., New York; Ralph Schwartz, Kings.

Bulletin No. 2

January 15, 1936

Since the issuance of our last bulletin the following bills have been introduced:

Senate Int. 220—Schwartzwald; Assembly Int. 215—Bush; amends the Public Health Law relative to vital statistics by providing among other things that still-births without attendance of a physician or midwife shall be treated as "deaths" without medical attendance. Referred to the Health Committee.

Comment: Introduced at the request of the Department of Health.

Senate Int. 233; Assembly Int. 200—Budget Bill. Appropriates \$10,000,000 for Temporary Emergency Relief Administration, \$6,000,000 being allocated to reimbursement fund to be used by municipal corporations and \$4,000,000 to the discretionary fund for direct grants thereto, administrative expenses, and for certain State improvements. Referred to the Finance Committee.

Assembly Int. 93—McCaffrey, amends the Workmen's Compensation Law relative to physical examination of employees, by striking out provision that physician, as employee or carrier may select and pay for, may participate in examination if employee or carrierate in examination if employee or carrierate.

rier so requests. Referred to the Labor Committee.

Comment: Mr. McCaffrey has sponsored this bill for a number of years. Last year it passed both houses but was vetoed by the Governor. We have always supported it.

Assembly Int. 188—Haskell, amends the Agriculture and Markets Law by empowering Department to regulate pasteurization and bottling of milk and making it unlawful to pasteurize or bottle milk for consumption in state which the dealer has sold at price less than minimum price fixed for such sales. Referred to the Agriculture Com.

Assembly Int. 204—Otto, adds new section 21-a to the Public Health Law, to permit employment of a local health officer to serve more than one town or village, service outside usual duties to be paid at per diem rate. Referred to the Health Committee.

Rumors that there will be a chiropractic bill persist, and newspaper clippings indicate there there is great activity among the chiropractors all through the State. Reports that a bill has been prepared and will be submitted have been carried in newspapers in Buffalo, Rochester, Brooklyn, and several places along the Southern Tier. Our information is that the bill will require examination from all applicants. None is to be licensed without examination, regardless of how long he may have been practicing in the State or the recognition he may have received in other states.

May we suggest that you "take time by the forelock" and warn your legislators while they are at home over this week-end regarding the imminence of this matter. Osteopaths and chiropractors agree that chiropractic is not osteopathy, and no one has ever defined chiropractic in such way that a recognized school could make it a part of its curriculum. Many anatomists, physiologists, and pathologists have studied the methods of chiropractors but none has been able to find a scientific basis for their claims. If there were even the smallest grain of virtue in chiropractic, it would have long since been recognized by some scientific group.

In the larger counties the chairmen can not personally see all of the legislators, but there they should assign members of their committees to certain legislators so that all will be adequately covered. Develop now your contacts so that they may be well established when we need them later on.

Public Health News

From the New York State Department of Health comes a "news letter" (No. 12, January 2, 1936) issued by the United States Public Health Service which is here reproduced in full with permission of Commissioner Parran. None of the cases described occurred in this State.

Poliomyelitis Following Vaccination Against this Disease

During the past year in the United States, several thousand individuals, mostly children, have received subcutaneous and intracutaneous injections of treated poliomyelitis virus in the hope of acquiring immunity against the natural disease. The two different forms of treatment to which the virus was subjected were intended to render it innocuous when thus used as a vaccine. those responsible for the production of these vaccines, through several health officers, and through others, word has come to the United States Public Health Service of the development, at suggestive intervals following these injections, of cases of paralytic poliomyelitis with high fatality. possibly subject to some correction, it is believed that the following statements represent closely the facts in each case.

1. A five-year old boy had his first symptoms of poliomyelitis six days after receiving the second dose of vaccine A in the left arm, the first dose having been given in the same arm twenty-seven days before the second. Paralysis began in the left arm the day after onset and death occurred after a three-day illness.

death occurred after a three-day illness.

2. A twenty-one month old girl received the second dose of vaccine A in the right arm twelve days after the first dose, and the onset of poliomyelitis occurred six days after the second dose. Paralysis began in the right arm three days later, and death occurred in five days

after onset.

3. A four-year old boy had his onset of poliomyelitis eight days after the first dose of vaccine A in his left buttock, and one day after the second dose at the same site. Paralysis began in his right leg two days later and is at present, after three months, confined to that extremity, though there is hope of ultimate nearly complete recovery.

4. An eight-year old girl had her onset of poliomyelitis eight days after the first dose of vaccine A in her left arm, and one day after the second dose in the same arm. Paralysis began in the arm two days later, and death

occurred after a three-day illness.

5. An eight-year old boy had his onset of poliomyelitis eight days after the first and only dose of vaccine A in his left arm. Paralysis began in the right arm two days later, and remained as a deltoid paralysis at last accounts.

6. A five-year old boy had his onset of poliomyelitis nine days after the first and two days after the record dose of practice.

6. A five-year old boy had his onset of poliomyelitis nine days after the first and two days after the second dose of vaccine A in his arm. Arm paralysis began two days later, and death occurred after a three-day illness.

- 7. A ten-year old boy had his onset of poliomyelitis ten days after the first dose of vaccine A in his left arm and three days after the second dose in the same arm. Paralysis began in the right arm the next day, and death occurred after a three-day illness.
- 8. A five-year old girl had her onset of poliomyelitis eleven days after the first dose of vaccine A in her right arm, and four days after the second dose in the left arm. Paralysis began in the left arm four days later and was still present at last accounts.
- 9. A fifteen-month old girl had her onset of poliomyelitis thirteen days after the first and only dose of vaccine B in the abdomen and developed general weakness four days later, which persisted at last report.
- 10. A five-month old boy had his onset of poliomyelitis fourteen days after the first and only dose of vaccine B in the abdomen and paralysis was first noticed nine days later. This paralysis persists at last report.
- 11. A six-year old girl had her onset of poliomyelitis fourteen days after the first, and seven days after the second, dose of vaccine A in her arm. Paralysis began in the left arm three days later, and complete recovery was questionable at last report.
- 12. A twenty-year old boy had his onset of poliomyelitis fourteen days after the first and only dose of vaccine B in his abdomen. Paralysis began two days later, and death occurred after a four-day illness. From this case poliomyelitis was transmitted to monkeys by Dr. J. F. Kessel.

Paralytic poliomyelitis was not epidemic in any of the localities at the time of the occurrence of these cases if these cases themselves are not included in the count. During the heaviest incidence of poliomyelitis in the community with the highest reported incidence, the expectation of paralytic poliomyelitis among those vaccinated within three weeks following vaccination, judging by its occurrence by age-groups in the community at large, was less than one-tenth of a case, yet a case occurred. At the other periods and in the other localities, the chance of a case occurring among the vaccinated was much less, yet in each instance cases occurred. The likelihood of the whole series of cases having occurred through natural causes is extremely small. In none of the cases was exposure to infection outside its own area known to be of special significance.

It is believed that to many physicians this series of cases, following by intervals of six to fourteen days the injection of one or the other of two different vaccines, renders undesirable the further use of polionivelitis virus for human vaccination at present

In every case where the injection was made in a limb and the sequence is known, the level of the spinal cord first affected corresponded to the extremity where the injection was made, paralysis beginning either in the same limb or in the contralateral This is strong support to other evidence that the virus of poliomyelitis is transmitted along nerve fibers, since neither blood nor lymph streams would afford direct access from one extremity to the correspond ing cord level. The remarkably high fatality in this series of cases was perhaps due to the part of the cord primarily infected being close to the nuclei corresponding to the muscles of respiration. The possibility is to be considered that a strain of poliomyelitis which has been subjected to prolonged monkey passage, with rather short incubation periods, is unusually virulent to man when administered by the subcutaneous or intracutaneous route. Though in a few of these cases it is possible or even probable that there was another intercurrent illness

in addition to poliomyelitis, in general the preparalytic symptoms were such as would be expected in poliomyelitis naturally acquired

In forming a judgment as to the applicability of a poliomyelitis vaccine, the not inconsiderable local and general reactions following its use need to be taken into account I It is also noteworthy that the appearance of neutralizing antibodies in the blood after the injection of poliomyelitis virus is very uncertain evidence of parallel immunity to the natural disease 2

Although any one of these cases may have been entirely unconnected with the vaccine, the implication of the series as a whole is clear

The above statement of cases is slightly amplified from that appearing in the Journal of the American Medical Association of December 28, 1935

¹ Gilliam, A. G., and Onstott, R. H. Results of Field Studies with Poliomyelitis Vaccine, read before the Southern Branch, American Public Health Association, St. Louis, November 19, 1935, Am Jour Pub Health, to be published 2 See also Schultz, E. Massachusetts Public Health Council Requires Differentiation in Reporting Paralytic and Non-Paralytic Poliomyelitis

By a recent vote of the Massachusetts Public Health Council it was determined that effective January 1, 1936, all cases of anterior poliomyelitis in that State shall be reported as "paralytic" or "non-paralytic (pre paralytic)" infections This action was taken in order to obtain so far as possible a true picture of the current prevalence of the disease as contrasted with former years when the non-paralytic cases were not reported to the same extent as they are at he present time

In the future all reports made by the Department of Public Health of Massachusetts will be in accordance with the classification above mentioned and supplemental reports will be filed as cases reported as pre-paralytic subsequently develop paralytic signs and the change in the classification is, therefore, necessary,

It is felt that this action of the Massachusetts Public Health Council is a progressive step in the right direction

GERMAN BIRTHRATE INCREASES

The impassioned campaign of Hitler for more babies in Germany has been rewarded by an increase of 224 per cent in the 1934 birthrate over 1933 The equally impassioned appeal of Mussolini was met by a fall of 08 per cent in the same period It should be added that, even so, the Italian birthrate is still much higher than the German

Physicians using their homes as offices are compelled in some cities to pay a higher rate for electricity than purely residential consumers, a rating that many doctors consider unfair The Medical Society of the County of Kings is organizing a protest of its members and hopes to secure a more reasonable charge.

Many children are suffering unnecessary eye trouble and injuries to the nervous system because of a general lack of adequate or properly controlled natural or artificial lighting in the schools, Dr. Hugh Grant Rowell, professor of health education at Teachers College, Columbia University, said a few days ago in a press interview.

Medical News

Bronx County

DR. MICHAEL J. LYNCH of the Bronx has been elected president of the medical board of St. Joseph's Hospital, of Yonkers.

Chautauqua County

Dr. W. L. Rathbun, superintendent of the Newton Memorial Hospital, Cassadaga, was elected president of the Chautauqua County Medical Society at its annual meeting on Dec. 18. He succeeds Dr. Thomas H. Shanahan. Dr. W. Gifford Hayward of Jamestown was elected first vice president, and Dr. Edgar Bieber and Dr. F. J. Pfisterer, both of Dunkirk, were re-elected secretary and treasurer, respectively.

Chemung County

DR. ARTHUR C. SMITH was elected president of the Chemung County Medical Society, succeeding Dr. La Rue Colegrove, at the ninety-ninth annual meeting on Dec. 18.

Dr. John F. Lynch was elected vice president, while Doctors William J. Cusick and George R. Murphy were re-elected treasurer and secretary, respectively.

Others elected were: Dr. Reeve B. Howland, state delegate; Dr. J. Lee Kinner. alternate delegate, and Dr. John H. Burke. Sr., censor.

Preparations were made for the centennial anniversary of the association next year.

Chenango County

Dr. W. L. Dodge of Afton was elected president at the 131st annual meeting of the Chenango County Medical Society. Dr. Wayland Mason was named vice president and Dr. John H. Stewart was re-elected secreary and treasurer.

Dr. E. W. Wilcox was elected delegate to the annual meeting of the state society and Dr. George L. Manley alternate. Dr. E. F. Gibson was elected censor for a three-year term.

Erie County

An illustration of the physician's tendency to risk his own health and even his life to care for his patients was seen in the death of Dr. John Leonard Eckel, of Buffalo, who rose from his sick hed to visit patients at a hospital on Nov. 26, and as he talked with one of them, while two nurses stood by, he straightened in his chair, sighed and died. Dr. Eckel was 55 years of age. He was on the staff of nine Buffalo hospitals as

attending and consulting neurologist and psychiatrist. He was president of the Buffalo Neuro-Psychiatric Society. He had been nominated for president of the Erie County Medical Society. He was associate professor of neurology and psychiatry at the University of Buffalo Medical School, and had been honored on countless occasions with invitations to read papers before scientific bodies in all parts of the world. His articles of research, numbering more than forty, have been published in European medical journals, principally in London, Berlin, and Vienna.

Greene County

THE GREENE COUNTY Medical Society entertained a visiting delegation of the Columbia County Society at a meeting in Catskill on Dec. 17 to listen to an address by Dr. David Moore, of New York City, on "Diabetes."

Kings County

Officers of the Kings County Medical Society were elected on Dec. 17 at a meeting of 200 members in the society's building. Dr. Henry Joachim, who takes office now as president, was elected a year ago. Dr. Thomas A. McGoldrick was chosen president for 1937. Others elected were Dr. John B. D'Albora, vice president; Dr. Joseph Raphael, secretary; Dr. Thomas B. Wood, associate secretary; Dr. Augustus Harris, treasurer; Dr. John A. McCabe, associate treasurer: Dr. Jacques C. Rushmore, directing librarian, and Dr. Edwin P. Maynard, associate librarian.

A FRANK EPITAPH, it seems, is already carved on the monument in the family burial plot where Dr. Edward T. Gibson, 81, formerly of Brooklyn, was laid to rest a few weeks ago. The plot is in an upstate city, and the inscription written by Dr. Gibson runs as follows:

"Well, we have got what was coming to us, and here in this burial plot we lie—us 14 skeletons of Gibsons, Tinkhams, Drakes, Pixleys and Curtisses, that once were clothed with flesh and lived and loved and laughed and danced and sang and suffered just like you till the God-created life-transmitting spark that had been passed down to us from the beginning died."

He served in the Philippine, Moro, Indian and Spanish-American Wars and was in the medical department of the Brooklyn Rapid Transit Company for 14 years.

Montgomery County

AT THE ANNUAL MEETING of the Montgomery County Medical Society in Amsterdam on Dec. 11, the following officers were elected: President, Dr. P. J. Fitzgibbons; secretary, Dr. W. R. Pierce; treasurer, Dr. S. L. Homrighouse; censors, Dr. W. H. Seward, Dr. R. C. Simpson, Dr. W. H. Rathbun, Canajoharie.

New York County

DR. CHARLES LOOMIS DANA, dean of American neurologists, professor of nervous diseases at the Cornell Medical College for over thirty years, died on Dec. 12 at Harmon-on-Hudson at the age of eightythree. He had practiced in New York City over fifty years and was the author of a "Textbook of Nervous Diseases and "Textbook of Nervous Diseases and Psychiatry" which is considered a standard work for consultation.

Dr. Dana was president of the Academy of Medicine, 1914-16, had served for years as chairman of its public health committee and was still a member of the board of trustees. He was also a former president of the American Neurological Association.

Rensselaer County

Dr. W. B. D. Van Auken was installed as president of the Medical Society of Rensselaer county at the society's 130th annual banquet held in the Hendrick Hudson

hotel, Troy, on Dec. 11.

Other officers installed included Dr. S. H. Curtis, vice president; Dr. Leo S. Weinstein, secretary; Dr. John F. Russel, treas-urer; Dr. J. D. Carroll and Dr. C. J. Handron, delegates to the state society; Dr. Katherine S. Cook and Dr. Elizabeth Palmer, alternates, and Dr. C. W. Hamm and Dr. William Trotter, censors.

Richmond County

Dr. Edward D. Wisely, who has been treasurer of the Richmond County Medical Society for a quarter of a century, retired at the annual meeting on Dec. 11. The members, in appreciation, presented him with a handsome Italian onyx desk set. Dr. Wisely made a very happy and graceful

speech recalling the society's early days. Officers for 1936 were elected. Dr. William C. Buntin, who had been vice president, was named president to succeed Dr. Driscoll, Dr. Frederick Schwerd was named vice president; Dr. Becker, treasurer; and Dr.

John J. Goller, secretary.
Dr. Pearson, Dr. Andrew J. McGowan
and Dr. Nathaniel Fedde were named to the board of censors; Dr. Herman Friedel,

member-at-large of the executive committee; Dr. Driscoll and Dr. Stanley Pettit, delegates to the state society; Dr. Anna Stein and Dr. Sara Bass, alternates; Dr. F. T. Donovan, delegate to the first district society; and Dr. C. J. DiCrocco, alternate.

Rockland County

Dr. J. WILLIAM GILES, seventy-four, Coroner of Rockland County, died at his home in South Nyack on Dec 17.

Dr. Giles had been president of the Rockland County Medical Society and was a director of the New York State Medical Society.

Suffolk County

THE OFFICERS of the Suffolk County Medical Society for 1936 are: President, Dr. David L. MacDonell, Sayville; First Vice President, Dr. Stanley P. Jones, Mattituck; Second Vice President, Dr. Earl M. McCoy, Central Islip; Secretary, Dr. Edwin P. Kolb, Holtsville; Treasurer, Dr. Grover A. Silliman, Sayville; Censors, Drs. B. P. MacLean, Huntington; William N. Barnhart, Central Islip; and Paul Nugent, East Hampton, Delegates to the State Society, Drs. Albert E. Payne, Riverhead, and Coburn A. Campbell, Port Jefferson. Delegate to Second District Branch, Dr. William H. Ross, Brentwood.

Tioga County

SIX FORMER PRESIDENTS of the Tioga County Medical Society gave interesting talks at a "Past Presidents' Night" on Dec. 10 at Owego. The following officers were elected for the coming year: President, Dr. Louis D. Hyde, of Owego; Vice-President, Dr. Corbet S. Johnson, Spencer; Sec .-Treas., Dr. Ivan C. Peterson, Owego; Censors, Dr. E. S. Beck, Owego; Dr. F. A. Carpenter, Waverly, and Dr. F. H. Spencer, Waverly; Delegate, Dr. G. S. Carpenter, Waverly; Alternate, Dr. A. C. Hartnagle, Berkshire.

Tompkins County

Dr. Henry B. Sutton was re-elected president of the Tompkins County Medical Society at the annual meeting at Ithaca on Dec. 17.

The business meeting was followed with a buffet luncheon and entertainment which consisted of the showing of several reels of motion pictures by Coach Nick Bawlf of

The other officers elected were Dr. H. L. VanPelt, vice president; Dr. B. F. Hauenstein, secretary, and Dr. Wilbur G. Fish, treasurer. Drs. David Robb, W. F. Lee, Hudson Wilson, Edgar Thorsland and E. F. Hall were elected censors.

Medicolegal

LORENZ J. BROSNAN, Esq.
Counsel, Medical Society of the State of New York

Malpractice—Treatment of Fractured Hip

A few months ago the Federal Circuit Court of Appeals for the Circuit which includes the far Western States reviewed upon appeal a malpractice case* involving the treatment of a fracture, and handed down an interesting decision exonerating the physician of the charges that had been made against him.

The case arose out of an injury which the plaintiff, a man fifty-nine years of age, received to his hip on May 28, 1931. He was taken in an automobile more than twenty miles over poor roads to the office of the defendant, Dr. M. for treatment. An x-ray picture of the injured hip was taken by Dr. M. and from that x-ray he diagnosed the condition to be an impacted complete fracture of the surgical neck of the right femur.

The doctor, according to his testimony, recommended hospitalization, and a special nurse, but the patient denied that such advice was given. At any rate the treatment was undertaken by the doctor without the patient entering a hospital or receiving the care of a nurse. Part of the care was administered in a hotel room near Dr. M.'s office. It was in such hotel room that after the diagnosis had been made the doctor placed the limb in splints and supported it by sandbags, as preliminary treatment to await the subsidence of the swelling which was present. After the swelling had gone down, apparently a few days after the injury, the physician applied a plaster cast to immobilize the leg in proper position. No other x-rays were taken before or immediately after the application of the cast. The reason given by Dr. M. for failing to obtain more such pictures, was that he claimed that he ascertained by measurement and examination by manipulation at the time of applying the cast, that the bones were still in the same position as in the x-ray he had already taken.

The account given of the fact situation thereafter indicates that the patient was taken home with the cast on his leg, and that in August 1931 the cast was trimmed away to some extent upon the order of Dr. M. He apparently attended the patient about eight weeks later and directed that the cast be removed by the wife of the patient. No x-rays were taken by the defendant after

the removal of the cast, and according to the patient's testimony, on January 28, 1932 after he had used crutches down to that date, he was told by Dr. M. to throw away his crutches and begin walking on his leg.

Subsequently in September 1933 the patient went to a Dr. H. who took an x-ray which showed that, at that time the femur had slipped past the head about two inches and that fibrous union connecting the head and the femur had occurred at such point of contact. Based upon the imperfect result that was concededly present in September 1933, the patient brought a malpractice suit for damages against Dr. M.

The case was tried in the United States District Court, and the trial resulted in a large judgment against the doctor, but that judgment was reversed by the Circuit Court of Appeals, which concluded after reviewing the case that the plaintiff had failed to show that he had been damaged by any malpractice. The said Court also ruled that the trial Court should have directed a verdict in favor of the defendant.

Upon the trial the first problem for determination was whether Dr. M. was negligent in the initial treatment of the patient. It was conceded that if the fracture was in fact impacted, the initial treatment was proper for a man fifty-nine years of age. However, the proof also was that if it were not impacted, and the broken ends of the bone were not in contact, the dislocation should have been reduced. The x-ray taken by the defendant was produced upon the trial, and defendant produced five expert witnesses who testified that the fracture was impacted. The only expert who differed on the interpretation of the x-ray was a Dr. R. who said he was unable to say whether or not it showed an impaction. Dr. R. was the physician upon whose testimony plaintiff primarily relied to make out his case. He was a young physician in his early thirties, who admitted that he had never had a case of fractured femur himself, and that he relied largely in his opinions as an expert, upon text books and his observations as an interne. He admitted having no special training in reading x-rays. However, he expressed the opinion that the fracture was unimpacted, giving as specific reasons his reading of the x-ray, the amount of pain

^{*} Moore v. Tremelling, 78 Fed. (2nd) 821.

suffered by the patient, and the fact that the plaintiff upon receiving the injury had been unable to bear weight upon the injured limb. He testified, against the contrary opinion of all the other experts, that if the fracture were impacted, the patient should have been able to stand.

Dr. R. however also testified that the end result which the plaintiff sustained would have been caused by walking too soon upon the leg. Dr. H. who took the 1933 x-ray, testified as a witness for the plaintiff, that the result may have been caused either from a failure to reduce the fracture or from a subsequent slipping after a proper reduction. The Appellate Court in ruling that negligence had not been established in connection with the initial treatment said in part:

We thus have plaintiff's witnesses assigning either or both of two causes for the defective union of the bone. If it could be said that the failure to reduce the fracture and the advice to the patient to use the leg prematurely were both negligent, it might not be necessary for the plaintiff to distinguish between the damages resulting from the two separate acts of negligence, but where one act is negligent and the other is not, the burden is upon the plaintiff to prove the damages which flow from the wrongful act.

In view of the opinion of the large number of professional witnesses to the effect that this was unquestionably an impacted fracture and was so shown by the x-ray pictures taken at the time, and in view of the fact that the opposing testi-mony of Dr. R. merely goes to the expression of his opinion that the fracture was unimpacted and does not purport to show that there was negligence in diagnosing the fracture as an impacted one even if we assume, as the jury may have believed and found, that the fracture was not reduced, it would still be true that we have nothing more in the case than an error of judgment and no proof that the appellant did not exercise such professional care and skill as were reasonably to be expected in that locality. There is no testimon that the locality. is no testimony that physicians in that locality were in the habit of taking more than one x-ray picture in the case of such a fracture or of making any examination other than that such as was made by the appellant. All the expert evidence is to the contrary. The plaintiff so far has failed to the contrary. has failed to show such an error of judgment in diagnosis as would justify a recovery. The treatment accorded the patient before the limb was placed in a plaster cast was in accordance with the diagnosis and conceded to be the correct treatment for an impacted fracture. If, for convenience, we divide the appellant's services into two stages, the initial treatment and the after treatment, and hold the former free from negligence and assume the latter negligent, then the evidence furnishes no basis for determining what result, if any, flowed from the latter and what from the former cause. The burden of proof is upon the plaintiff not only to show negligence but also the damage resulting therefrom.

The Court in reviewing the case so far as the charges of negligent advice as to weight-bearing was concerned, ruled that a proper case had not been made out on that point saying in part:

Plaintiff asked the witness to further define the treatment which he considered improper. In response he testified concerning after treatment that no more x-ray pictures were taken, that the cast should have been removed by a licensed physician, that the physician should not have discontinued his treatment of the patient so long as the patient was having severe pain, and added, "I think it was improper to tell him to walk without a picture being taken, there being no way of telling exactly the position of the bones without a picture to show the position."
Dr. R. thus specifies that the improper treatment so far as the premature use of the limb is concerned was in allowing the limb to be used at all without an x-ray picture. He does not testify and there is no evidence to the effect, that the use of the limb was premature, if in fact it was. There is a failure to show that the result complained of was proximately caused by the failure to take an x-ray picture, which was the only act of negligence claimed in this respect. As we have said it is necessary, not only to establish neglect on the part of a physician, but also to show that the injuries complained of resulted from that neglect. It is not shown that the use of the limb was premature, and consequently no recovery can be had for the advice to use the limb in January 1932.

Finally the Court ruled that even assuming negligence in both the initial treatment and the after-care, the plaintiff still had failed to prove he had sustained any damage as a result, saying in the opinion:

Moreover, even if we assume that both the initial treatment and the subsequent care of the plaintiff were negligent, there is a fatal defect in the proof because it is not shown that proper treatment would have produced a better result. Such evidence is essential in a malpractice case where two causes are cooperating to produce the final result—one, the fracture of the bone, with the attendant injuries, and the other the im-proper treatment. The burden is upon the plaintiff in a malpractice case to prove that the injuries he complains of resulted from the latter cause and not the former. The jury cannot be permitted to speculate upon the relative amount of injury due to the fracture and that due to the malpractice. There must be some evidence to distinguish the injury due to the fracture and that due to the appellant's negligence. It cannot be assumed that, in the absence of malpractice the result would have been better, it must be shown by the evidence of expert witnesses. The expert testimony showed that a fractured hip in the case of a person of plaintiff's age, is very serious, resulting in death in about fifteen per cent of the cases, and that in cases of all ages suffering from such a fracture, only about fifteen per cent fully recover; that in the balance of seventy per cent there was functional impairment of greater or lesser degree. There is no evidence to justify the conclusion that the plaintiff belonged in the fifteen per cent of cases which make a complete recovery. His age, the proximity of the fracture to the head of the femur, the fact that the senovial fluid contacting the fracture tends to prevent union, and the fact that he was suffering from a nervous disorder at the time of the accident all tend to exclude

him from the percentage that make a complete recovery. In any event it is clear that the preponderance of probability was against a perfect result in the plaintiff's case and that considerable impairment was reasonably certain to result from the injury with the best of care and medical attention.

Across the Desk

Is National State Medicine Unconstitutional?

If More or Less consternation struck the authors of the A.A.A. in Washington as they read the Supreme Court's decision relegating it to the junk-pile, we may wonder what the feelings were over in the Department of Labor, where the Secretary must have seen in the decision several points that apparently apply equally as well against her pet scheme of state medicine. In fact, as plan after plan of the Washington socializers is shattered on the granite negation of the Supreme Court, any further projects emanating from their bright young minds begin to look more and more doubtful and invalid.

The Court went so far, indeed, as to suggest a number of similar designs that might be enacted into law under our new political gospel, and branded them all as "prohibited ends" under the Constitution. "Until recently," the Court remarked rather meaningly, "no suggestion of the existence of any such power in the Federal Government has been advanced," but now it is argued that Congress has the power "to tear down the barriers, to invade the States' jurisdiction, and to become a parliament of the whole people, subject to no restrictions save such as are self imposed. The argument, when seen in its true character and in the light of its inevitable results," declares the Court, "must be rejected."

It is hardly necessary to say that the project for state medicine is part and parcel of the new gospel, and the words quoted above sound almost like a notice served on the "brain trust" not to waste the Court's time with any further socialistic contrivances and stratagems that violate our fundamental law and run counter to our system of government.

The Doctor's Freedom to Join or Starve

LET US RYN OUR EYE over the A.A.A. decision, and try to see as well as we can what the Court would say if it were passing on an act to regulate the doctors, instead of on one to regulate the farmers. "Put yourself in his place," is an old maxim, so suppose

that we put the doctor in the farmer's place in this decision, and see what happens. Well, the Court reminds us that "the United States is a Government of delegated powers," so "it follows that those not expressly granted, or reasonably to be implied from such as are conferred, are reserved to the States or to the people. . . . Powers not granted are prohibited. None to regulate agricultural production [or the practice of medicine] is given, and therefore legislation by Congress for that purpose is forbidden."

Nothing could be much clearer or more

apropos than that.

The A.A.A. was ostensibly a taxing act. It laid a tax on processers and paid the proceeds to those farmers who complied with its regulations. The Court ruled that this was not a true tax "for the general welfare," as stipulated in the Constitution, and quoted in support a previous ruling that "the power to tax could not justify the regulation of the practice of a profession, under the pretext of raising revenue." Yet that is precisely what a scheme for state medicine would attempt. It would levy assessments on employers and employees to provide a fund for medical care of employees in need of it.

But every doctor would be free to join or not, as he liked, some say, so that the profession would not be "regulated" or "regimented," as charged. No? The Supreme Court, as it happens, took up that very point. The farmer could comply or not, as he pleased, with the A.A.A., but "the price of such refusal is loss of benefits. The amount offered is intended to be sufficient to exert pressure on him to agree to the proposed legislation." In the case of a doctor in an industrial district, he could join in the state medical scheme or see all his patients sent to other doctors who did join. He would have entire freedom to join or starve. As the Court very truly remarks: "The power to confer or withhold unlimited benefits is the power to coerce or destroy. . . . The result may well be financial ruin. . . . This is coercion by economic pressure. The asserted power of choice is illusory."

So we see how that argument would fare if the state medical plan reached the High

Do Not Stack the Guns Too Soon

If we are still thinking of our friend the Secretary of Labor, we shall remember that she is sud to be one of the projectors of the great national medical survey now in progress. It is also said that if the survey reveals a large amount of sickness lacking medical care, as is fully expected, that fact will be used to argue the need of state medicine to provide it. That is, we may say, local conditions or needs throughout the nation will create a situation of national concern, or an emergency, requiring Federal action.

Did the Supreme Court happen to say anything in its verdict on the AAA to cover this point? It did It remarked "It does not help to diclare that local conditions throughout the nation have created a situation of national concern, for this is but to say that whenever there is a wide-spread similarity of local conditions Congress may ignore constitutional limitations upon its own powers and usurp those reserved to the States"

Altogether, and by and large, and taking one thing with another, it cannot be said that the AAA decision brings any special hope or joy to the medical socializers' camp In fact, it seems to bring them a rather large cargo of just the opposite But it will not do to stack our guns too soon Thus far the New Deal legislation has apparently been concocted with little regard for the Constitution, and more may follow the same path If an act is passed setting up a structure of state medicine, many a doctor's practice can be badly upset before the act reaches the supreme tribunal. The best plan is to keep it from ever going on the statute books-stop it before it starts

The "Low-Down" on "Red Medicine"

THE PLAUDITS SHOWERED on the Soviet medical system by the authors of "Red Medicine" and others are coming to look more and more ridiculous as the real facts are known The American doctors who attended the International Physiologic Congress last summer in the land of Lenin are now telling what they found over there, and the idea that America ought to pattern its medical system on Russia's is really comic One of the visiting physicians was Dr Arnold L Lieberman, of Gary, Ind, who describes the Russian medical situation in the AMA Journal

The first step of the Soviet revolutionaries in founding their ideal state was to abolish the upper and middle classes, and as these included the doctors, they were "liquidated," 1e executed or driven out of the country That was "red medicine" beyond a doubt As Dr Lieberman remarks, 'little of the medical personnel was left" Quite naturally the next thing was that wave after wave of cholera typhus, malaria, and similar scourges swept the country so fatally that the wise men of Moscow decided it might be a good idea after all to have some doctors A happy thought So the authorities proceeded to organize 'rapid courses" of training, paying the student's way, but requiring him to go to any post designated for the next five years

True this is providing the country as a whole with doctors of a certain sort for the first time in its history, but the doctors are described as no better than superior nurses here. They are coping as best they can with the various plagues, and the health and mortality figures are naturally much better than they were fifteen years ago, when there were virtually no doctors at all. This should be kept in mind when glorifiers of the soviet system begin to quote statistics.

Here is the best that Dr. Lieberman can say for the rural doctor in the village or country "The young medical graduate is better than nothing at all and he certainly is a focus of some sanitary instruction. One can see that in his crude little room or two he is doing excellent pioneer work in small-pox and typhoid control, child care, elementary sanitation, civilizing habits of cleanliness and so on. While, on the average, he is doing no surgery and committing countless errors of diagnosis and treatment still he is a beneficent village influence that was absent twenty years ago."

In the cities the situation is much better, but the doctors are not described as being any abler, except for the very few survivors of pre-war days, who now "unquestionably command an outstanding niche in soviet society"

Other American physicians who visited Russia tell us that more than half of the medical students are women, as the young men with a scientific bent find the rewards in engineering and mechanical fields far superior to those in medicine

To put it in a nutshell, the Soviet government, in a desperate effort to combat devastating plagues, has turned out thousands of half-educated "doctors" and scattered them across the land, here, there, and

everywhere, to do the best they can. In the cities a system is arranged by which any one who likes can summon one of the "doctors" at any time.

That is what we are asked to copy as something far above what we have here! The next speaker who can keep his face straight while he advocates it ought to have a large medal.

Big News that is No News

A LITTLE IMAGINATION can easily picture the people of this country exposed to enemies on all sides, within and without, ready to spring, and kept at bay only by the most untiring and unremitting vigilance. The report just issued by the Surgeon General of the U. S. Public Health Service recalls a sinister fact that most of us never even think of—that cholera is continually raging in Asia and the near-by islands, and might easily attack our shores but for the eternal watchfulness of our health officers. In 1934 there were nearly 300,000 cases just across the blue Pacific, with nearly 150,000 deaths. Bubonic plague, too, is present in nearly all parts of the world, and 100,000 cases of typhus fever were reported in various lands, many of them in our own hemis-"Yellow Jack," a terrible scourge in this country within the memory of people now living, still claims its victims in South America and Africa.

Our own home-grown communicable diseases are too well-known to require comment, but all may not realize that in a mere 35 years we have cut the death rate of typhoid fever from 35.9 per 100,000 to 3.3, and the death-rate of diphtheria from 43.3 to the same low figure. In other words, there are 91,000 fewer deaths per year now from these two causes than if the 1900 rates prevailed! More lives are saved every year in this war than were lost by battle wounds in our clash of 1917-18, and the doctors would well deserve, like the veterans, a bonus of billions for their services in this great victory, instead of being threatened with a draft into some ill-paid state medical scheme.

The American people have come to take all these brilliant medical achievements as a matter of course, and the saving of enough lives to repeople Utica or Schenectady every year arouses no excitement whatever. A splendid opportunity is open to any writer who can bring vividly before the nation the marvelous rescue-work going on day and night, snatching people from the

brink of the grave just as truly as if ships were sinking or houses blazing, but all done with a true professional absence of show or brag which really makes it more, instead of less, dramatic.

Let no Coin Escape!

THE NATIVE INGENUITY that comes to the rescue in a crisis is illustrated in several incidents told by a member of the dental branch of the healing art, Dr. Egbert A. Clark of Washington, D. C., in Dental Items of Interest. The first incident concerned William Plimsoll, originator of the "Plimsoll Line" on ships, to denote how deep they may be loaded. One day, it seems, a coin slipped down Mr. Plimsoll's throat, lodged there, and caused considerable coughing and distress. A reversible frame, like a blackboard frame, was nearby, Mr. Plimsoll had himself strapped to it, then he was tipped up, head downward, coughed two or three times, and out came the coin. Dr. Clark read the story.

Years later a gold crown which he was cementing on a patient's tooth slipped from Dr. Clark's fingers and went down the patient's throat. In a flash the story of Plimsoll same to the dentist's mind, he reversed his patient on the dental chair so that he lay on his stomach with his head on a pillow on the foot rest, and his feet tied to the head rest with two towels. When the patient coughed, the dentist tipped the chair. Once, twice, thrice, and on the third try, the crown gave a welcome tinkle as it hit the foot rest.

Two years passed, and Dr. Clark was visiting a medical friend in Virginia when three horsemen rode up to the doctor's door. "One of them was coughing violently and was in great distress. He had inhaled a ten cent piece and it had gone into his bronchus. He had been to two or three doctors but had gotten no relief. Doctor W. was at his wits end as he did not know what to do, I suggested the Plimsoll method. We took the door off the woodshed, also the strap hinges, and fastened the door to the kitchen table with the strap hinges. I had the young man lie down on the door on his stomach, tying his feet to the upper end of the door. When a fit of coughing came on, we tipped him up, and it took several 'tip-ups' before it came up, which it did, much to his relief.

"The ten cent piece had been in the bronchus so long it was covered with a secretion which prevented it slipping away easily."

February 1, 1936]

It might be a good plan to loosen the screws in the hinges of the office door, to be ready for emergency, as this is no time to let any coins get away without making every possible effort to retrieve them.

Making the Doctor the Goat

THE BEST THING THAT has been said yet about the much-mooted "mercy killings" came the other day from the keen Yale professor of physiology, Dr. Howard W. Haggard, in a lecture at Rochester. The proposal that the doctors end human life in certain cases is to make the physician a public executioner, he declared. "In criminal courts," he said, "judges are not asked

to knock a murderer over the head," and "the public cannot ask the medical profession to kill patients believed incurable. The executioner's post is on a low level, and to ask physicians to assume it is to insult the profession."

It might be added that while it may take a physician to save life, it does not need a physician to end it, and if the family or the patient is so anxious for death, they are perfectly able to bring it about and should take the responsibility. The game of trying to find a scapegoat is as old as the human race, and this looks a lot like making the doctor the goat. The responsibility should be gently but firmly put back where it belongs.

Books

Nutrition Work with Children. By Lydia J. Roberts. Second edition. Octavo of 639 pages, illustrated. Chicago. University of Chicago Press, 1935. Cloth, \$4.00.

In reviewing this book one must consider its object. One sentence in the Foreword reads: "This book is published primarily, then, to be used as a text and reference book in our own University classes or for similar ones, etc."

As such it is a book for teachers and presents the problem and the broader aspects of malnutrition rather than the detail.

The bibliography is enormous, even when duplication is considered, as it is recorded by chapters.

As a second of the problem, great value to great, in the main, it is written for other students.

W. D. LUDLUM

Anaesthesia and Analgesia in Labour. By Katharine G. Lloyd-Williams, M.D. Duodecimo of 96 pages, illustrated. Baltimore, William Wood & Company, 1934. Cloth, \$2,00.

This small pocket size book of one hundred pages gives a very comprehensive review of analgesia and anesthesia in labor.

The author first discusses the drugs used for analyssia during the first stage of labor, and she briefly gives the indications and contra indications for the use of the various drugs and their effect upon the patient.

For second stage analgesia and anesthesia, she discusses the various forms of inhalation, intravenous, and intra spinal anesthetics which are in common use.

The author does not forget that anesthesia

during labor may cause a "sleepy" baby, and she discusses briefly the various methods of resuscitation for the new born infant.

A final chapter is devoted to the choice of anesthetics for use in labor complicated by toxacmias, cardiac disease, tuberculosis and diabetes.

The volume is small, very readable, and gives an excellent summary of the subject.

W. S. SMITH

The Care of the Aged, the Dying, and the Dead. By Alfred Worcester, M.D. Duodecimo of 77 pages. Springfield, Ill., Charles C. Thomas, 1935. Paper, \$1.00.

These lectures formerly appeared in a book now out of print, "Physician and Patient," L. Eugene Emerson, Editor, and are now republished in answer to requests for reprints, the supply of which was exhausted.

In the treatment of the aged, the author shows that tact, understanding and kindness are often of more value than very scientific treatment and cites examples to prove this,

To the author, the natural return of the body to the dust is more to be desired than its preservation for years in a metallic casket buried in cement.

Attention is called to the growth of ridiculous extravagance in expenditure for overpriced and elaborate coffins and funerals from the desire to pay respect to the dead and to the desirability for the promotion of more reasonable burial customs.

The author is a writer of culture and a treats of subjects not often discussed.

W. E. McCollom

everywhere, to do the best they can. In the cities a system is arranged by which any one who likes can summon one of the "doctors" at any time.

That is what we are asked to copy as something far above what we have here! The next speaker who can keep his face straight while he advocates it ought to have a large medal.

Big News that is No News

A LITTLE IMAGINATION can easily picture the people of this country exposed to enemies on all sides, within and without, ready to spring, and kept at bay only by the most untiring and unremitting vigilance. The report just issued by the Surgeon General of the U.S. Public Health Service recalls a sinister fact that most of us never even think of-that cholera is continually raging in Asia and the near-by islands, and might easily attack our shores but for the eternal watchfulness of our health officers. In 1934 there were nearly 300,000 cases just across the blue Pacific, with nearly 150,000 deaths. Bubonic plague, too, is present in nearly all parts of the world, and 100,000 cases of typhus fever were reported in various lands, many of them in our own hemisphere. "Yellow Jack," a terrible scourge in this country within the memory of people now living, still claims its victims in South America and Africa.

Our own home-grown communicable diseases are too well-known to require comment, but all may not realize that in a mere 35 years we have cut the death rate of typhoid fever from 35.9 per 100,000 to 3.3, and the death-rate of diphtheria from 43.3 to the same low figure. In other words, there are 91,000 fewer deaths per year now from these two causes than if the 1900 rates prevailed! More lives are saved every year in this war than were lost by battle wounds in our clash of 1917-18, and the doctors would well deserve, like the veterans, a bonus of billions for their services in this great victory, instead of being threatened with a draft into some ill-paid state medical scheme.

The American people have come to take all these brilliant medical achievements as a matter of course, and the saving of enough lives to repeople Utica or Schenectady every year arouses no excitement whatever. A splendid opportunity is open to any writer who can bring vividly before the nation the marvelous rescue-work going on day and night, snatching people from the

brink of the grave just as truly as if ships were sinking or houses blazing, but all done with a true professional absence of show or brag which really makes it more, instead of less, dramatic.

Let no Coin Escape!

THE NATIVE INGENUITY that comes to the rescue in a crisis is illustrated in several incidents told by a member of the dental branch of the healing art, Dr. Egbert A. Clark of Washington, D. C., in Dental Items of Interest. The first incident concerned William Plimsoll, originator of the "Plimsoll Line" on ships, to denote how deep they may be loaded. One day, it seems, a coin slipped down Mr. Plimsoll's throat, lodged there, and caused considerable coughing and distress. A reversible frame, like a blackboard frame, was nearby, Mr. Plimsoll had himself strapped to it, then he was tipped up, head downward, coughed two or three times, and out came the coin. Dr. Clark read the story.

Years later a gold crown which he was cementing on a patient's tooth slipped from Dr. Clark's fingers and went down the patient's throat. In a flash the story of Plimsoll same to the dentist's mind, he reversed his patient on the dental chair so that he lay on his stomach with his head on a pillow on the foot rest, and his feet tied to the head rest with two towels. When the patient coughed, the dentist tipped the chair. Once, twice, thrice, and on the third try, the crown gave a welcome tinkle as it hit the foot rest.

Two years passed, and Dr. Clark was visiting a medical friend in Virginia when three horsemen rode up to the doctor's door. "One of them was coughing violently and was in great distress. He had inhaled a ten cent piece and it had gone into his bronchus. He had been to two or three doctors but had gotten no relief. Doctor W. was at his wits end as he did not know what to do, I suggested the Plimsoll We took the door off the woodshed, also the strap hinges, and fastened the door to the kitchen table with the strap hinges. I had the young man lie down on the door on his stomach, tying his feet to the upper end of the door. When a fit of coughing came on, we tipped him up, and it took several 'tip-ups' before it came up, which it did, much to his relief.

"The ten cent piece had been in the bronchus so long it was covered with a

Surgical Pathology of the Peritoneum. By Arthur E. Hertzler, M.D. Octavo of 304 pages, illustrated. Philadelphia, J. B. Lippincott Company, 1935. Cloth, \$5.00.

This is the sixth of Dr. Hertzler's monographs on Surgical Pathology, in book form, 301 pages and 201 illustrations. to the chapters on anatomy, the healing physiology, of peritoneal wounds, peritoneal adhesions, and the seven devoted to a detailed consideration of the various types of peritonitis, are the last three chapters on mesenteric thrombosis and diseases of the blood vessels, diseases the omentum and tumors of the peritoneum, mesentery, omentum and retroperitoneal space.

This detailed discussion of the diseases of the peritoneum is, as the author states, the results of 40 years of constant companionship with this form of pathology. The consideration of the formation and the significance of adhesions seems to have been a special study by the author. His observation that "to mistake an unusual peritoneal fold for an adhesion is both to execute needless procedures and to invite failure to find the real lesion" is of considerable clinical value.

It is evident that the author of this monograph is strongly opinionated on the interpretation of his findings, but the critical thoroughness and the scientific care with which he conducted his studies would seem to justify his opinions. The monograph is, withal, a very readable book,—and quite profitable reading, too.

J. RAPHAEL

The Treatment of Common Female Ailments. By Frederick J. McCann, M.D. Third edition. Octavo of 379 pages. Baltimore, William Wood & Company, 1934. Cloth, \$4.75.

The purpose of this book is for a guide to the treatment of woman's ailments frequently met with in a general medical

practice.

In this third edition the text has been revised in order to make it more serviceable to the general practitioner, and several new chapters have been added. The text is for the most part, a record of the observation and experience of the author, and he has succeeded in writing a very excellent volume which should be very helpful to the general practitioner.

The chapter on Fertility and Sterility is of particular note. The author presents the subject in a clear and concise manner, and latest theories and practice are carefully

explained.

A study of this volume will show how much can be achieved in relation to the prevention of female diseases, and that this early recognition and prompt treatment is the chief means to that end.

W. S. SMITH

The Medical Clinics of North America. Vol. 18, No. 3. November, 1934. (New York Number) Octavo. Published every other month by the W. B. Saunders Co., Philadelphia. Per Clinic year (6 issues). Cloth, \$16.00; Paper, \$10.00.

This publication is fortunate in possessing articles that are not only conclusive in their interpretations but also brief in their discussion. Of particular mention is the symposium on lymphadenopathy which is discussed admirably from a clinical and therapeutic aspect. One is also impressed with the subjects dealing with "heart failure" and with a very instructive article dealing with the relationship of the thyroid gland to Graves' Disease.

The publishers announce that these Clinics will in the future, feature the every-day problems of the general practitioner. In the Clinics, presented diagnosis and treatment will be emphasized. In this change of presentation, the clinical side will be stressed. Any improvement in this well established publication will be welcomed by

the profession.

RUDOLPH CHESS

IVolume 36

Diagnosis and Treatment of Skin Diseases Including the Care of the Normal Skin. By Jacob H. Swartz, M.D. & Margaret G. Reilly, R.N. Octavo of 316 pages, illustrated. New York, The Macmillan Company, 1935. Cloth, \$3.50.

Here is a book that is distinctly different in that it has been written by a dermatologist, and a nurse who has been especially trained in the care of dermatological

patients.

To the student it is of great value because of the arrangement of the text. The preliminary chapter dealing with the anatomy, physiology, and elementary lesions of the skin, is concise. Later chapters contain the dermatoses according to the area predominantly involved, and these diseases are sufficiently described for general purposes.

The practitioner will derive great benefit from carefully reading the chapter on Care of the Normal Skin which explodes many of Aunt Mollie's pet theories, and tells him what he can properly advise his patients in regard to soaps, cosmetics, hair dressing, etc. Under the treatment of the diseases the actual nursing care is described in many instances so that the physician may correctly, and minutely, outline the care to his patient, or her attendant.

The entire book, which contains also chapters on the examthemata, and on syphilis, is commendably written, and well illustrated with 66 plates, as well as figures illustrating scalp, foot, arm and hand dressing, and face masks.

The book may, also, be profitably used by nurses in their course of study.

CHARLES B. TOWNS HOSPITAL

FOR THE EXCLUSIVE TREATMENT OF

ALCOHOLISM and DRUG ADDICTION

This hospital has specialized solely in addictions for over thirty years. Our experience has shown us that best results could not be obtained when associated with any other type of case. Its method of treatment has been fully described in the journal of the American Medical Association and other scientific literature. The treatment is a hospital procedure and provides a definite means of eliminating the craving and the toxic products of alcohol and drugs. Emphasizing the after care and with appreciation of the seriousness of the alcoholic problem we devote the convalescent period to minimizing the possibility of relapse. In the classification of the City of New York hospitals this institution has been granted a special license by the Commissioner of Hospitals for the exclusive treatment of alcoholic and drug addiction.

Carriage and Culture

A man and his wife with greying hair sat is the lobby of a large hotel watching the young people arrive for an evening party.

"Some very fine gowns there," said the man.

"Yes, but the girls don't know how to carry them," replied his wife. "Not one girl in ten here tonight knows how to walk. That was one of the things we had to learn when I was at boarding school. You can always tell a cultured, well-bred girl by the way she carries herself. Nine-tenths of these girls walk in a slouchy, sloppy way that marks them at once as below par socially."

A graceful step, combining elegance and harmony with ease of action and attitude, creates a favorable impression instantly, and it can be learned by any young woman with proper instruction. It is one of the things

invariably taught in the best girls' schools and, combined with many other elements, produces the girl who is "well turned out" and is able to take her place in any sphere of society.

In the same way the military or semimilitary training in many boys' schools produces a young man with square shoulders, chin up, spine erect, and a step that is strong, springy and firm, and makes everyone who sees him say, "What a fine young fellow." In the keen social and business competition today these matters count. A careless, awkward, ungainly gait makes an unfortunate first impression that may be decisive.

Then, too, who can deny that fine habits of walking and carriage have their effects on habits of the mind? The man who steps with firm, strong tread will naturally develop a strong, decisive way of thinking and acting. The girl who moves with grace and harmony will acquire the social ease of a cultured woman.

Education means more than books. It takes in the whole life and training of the growing boy or girl, and our best schools neglect no part of it.

THE TRUE ECONOMY OF DEXTRI-MALTOSE

It is interesting to note that a fair average of the length of time an infint receives Dextri-Maltose is five months. That these five months are the most critical of the baby's life. That the difference in cost to the mother between Dextri-Maltose and the very cheapest carbohydrate, at most is only \$6 for this entire period-a few cents a day That in the end, it costs the mother less to employ regular medical attendance for the baby than to attempt to do her own feeding, which in numerous cases leads to a seriously sick baby eventually requiring the most costly medical attendance - Adv

Travel and Hotels

See What You've Heard About Bermuda

On February 4th, the Bermuda Festival of Sports and Fashions will open at one of the most famous spots in the country-the British Empire building at Rockefeller Center in New York City, and will continue for one month.

prospective to interest both Bermuda-bound travelers and those lucky individuals who have already vacationed on this glorious coral island, the Bermuda Festival will feature well known activities along with interesting Bermudian sidelights the most sightseeing-minded visitor is apt to miss.

For ladies who plan to give up dusting and menu planning for beach lolling (and that on the grandest pink beaches we know of) there'll be fashion shows to illustrate the current vogue

in lolling costumes.

For tired professional and business men who long to get away from it all, there'll be irresistible pictures of rolling Bermuda fairways and phenomenal Bermuda water quarry.

For everybody-from seven to seventythere'll be lectures on and pictures of idyllic bicycle tours, where to stop for a snack, to play tennis and golf, to ride horseback-in a wordwhere to indulge your particular hobby.

Perhaps you are a camera addict. If so, you'll be intrigued by a display of camera studies, made in Bermuda, not only for their own merit but also for the fact that they'll give you a general idea of the wealth of scenic subjects you can experiment with on your own trusty kodak.

Perhaps you are a placid soul whose only wish is to take your ease behind a team of spanking bays and drive leisurely from Devil's Hole to Wreck Hill, and so about the island.

If you are planning a trip within the next few months, there'll be travel agents on hand with whom you can discuss rates and sailings. If you are a seeker of facts-there will be books on Bermuda architecture, gardens, climate, history and customs. There's everything to learn about Bermuda-from Walter Beebe's famous undersea exploration to the pros and cons of a rum swizzle-and here is the best place to get this information.

Infant in arms or captain of industry, you'll enjoy this elaborate Bermuda revue.

Boats Just Don't Like Him

The "Fates" probably have to indulge in an

occasional prank, but why they insist in playing their jokes on a man who has earned the right to a tranquil vacation is beyond the ken of Mr. Walter W. Lee, advertising manager of the Knott Hotels.

A year of energetic work and a part in the tremendous success of the Knott Hotels earned him the management's reward of a winter vacation.

Being a man of tempered and conservative ideas. Mr. Lee chose to spend the vacation in such a manner and to refrain from the usual formalities attached to vacationing. Selecting a cruise scheduled by the Standard Fruit Line for mid-January, he arranged for passage on the S. S. Gatun. Two weeks before the sailing date, he was notified that this steamer had been withdrawn from service.

Still light-hearted, Mr. Lee decided to book passage on the S. S. Atlantida, another Standard Fruit boat. And again, two weeks prior to sailing, he was notified that the Atlantida was being withdrawn from service. But with all the optimism of a Hollywood aspirant and the persistency of a feminine opinion, Mr. Lee turned to the Savannah Line and a sail to the sunny climes of his own country. Woe upon woe-for a third time he was regretfully informed that the steamer was being withdrawn from service.

Now Mr. Lee is wondering if there is conspiracy afoot against his trodding the decks of a steamer and if travelling incognito would clear up his difficulties in getting under way.

A "Suburb" of the Democratic Convention

Atlantic City will practically become a suburb of Philadelphia, during the Democratic Convention.

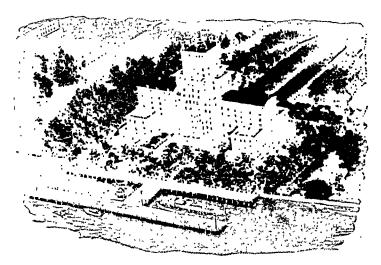

One of the major inducements put forth by the city of Philadelphia in its successful efforts to secure the national Democratic convention was its nearness to Atlantic City, and with the full cooperation of the seashore resort and the City of Brotherly Love, the Democratic convention will afford delegates opportunities for both work and play such as no other meeting place has been able to offer.

For many of the delegates, the convention will take on a holiday air since they plan to bring their families to Atlantic City during the convention and will themselves take advantage of the excellent transportation service, that

will be in effect at that time, to combine convention business in Philadelphia with rest and recreation in Atlantic City where beach and boardwalk are famous.

Austrian Travel

In a change of name and address, the Austrian State Tourist Department (formerly the Austrian National Tourist Office) calls attention to the festivals this coming summer.

The one at Vienna is from June 7th to 21st. the Bruckner Festival at Linz will be held July 18th to 21st, one at Salzburg, July 25th to August 31st, and the Passion Play at Thiersee is scheduled for every Sunday from May to September, inclusive.

Go South in Air-Conditioned Comfort

"Go South in Air-Conditioned Comfort," is suggested by the Seaboard Air Line Railway.

Air-conditioning is as necessary in winter as it is in summer in order to have healthful, uniform temperatures throughout your journey -to heat the air while traveling through cold climates-to cool it in Florida's warmth.

Air-conditioning is extremely important in any season to provide filtered and purified air -free from dirt, dust, cinders, and germs; to humidify the air to the most comfortable bodily reaction-and to constantly circulate the clean, tempered air-without dangers of hot, stifling dry heat or drafts.

The Seaboard Air Line suggests also taking your auto along, and enjoy the use of it while south without the possible dangers and strains of driving it there through states that have snows and sleet that make the roads hazardous. When two or more people travel on tickets good in Pullman cars, only one extra ticket is required for the shipment of your automobile. No crating or packing is necessary-just drive your car to the freight station-drive it away at your destination.

One of your greatest pleasures during your winter sojourn can be your trip to and from the South. The Seaboard Air Line's luxurious, completely air-conditioned trains offer you the finest in transportation, and there's a fare to fit every purse in the reduced winter excursion fares now in effect whether your stay is for a few days or the rest of the season.

Penny-a-mile Railroad Fares

Penny-a-mile railroad fares, generally considered one of railroading's Utopian dreams, recently went into effect in England.

(Continued on page xxxiv)

THE FAMOUS WORLD CRUISER

Warint SAILS EVERY SATURDAY

FEBRUARY 8, 15, 22, 29

MARCH 7, 14, 21, 28

Sunlight or moonlight, it makes no difference in Nassau, so far as the sheer joy of being alive is concerned. Days are filled with things you wish to do, from the most active sports to the laziest loafing in the world, and the pleasantest. In the evening there are dancing, gay parties and smart social gatherings, warmed by the hospitality of these friendly latitudes and flavored with old-world courtesies. Truly, it is good to be alive, and in the Bahamas.

Every Saturday until March 28th special 6 day cruises sail from New York, with a daylight day and evening in Nassau, for as low as \$70 with the famous world cruiser Carinthia as your hotel. Also 13-day tours including hotel room and meals in Nassau (rates on application). For longer vacations, the oneway fare is as low as \$65; round-trip fares, with stonover privileges, and return by later sailing of the luxurious Carinthia, as low as \$95. No passports.

Ask your Local Travel Agent about the Cunard White Star Deferred Payment Plan or Consult Cunard White Star Line, 25 Broaduay, or 638 Fifth Atenue, New York . . . or Nassau, Bahamas, Inform Bureau, 30 Rockefeller Plaza, N. Y.

(Continued from page xxxiii)

Two great British railroads, the Great Western and the London, Midland and Scottish, as an experiment abolished the minimum Monthly Return Ticket fares in the South Wales industrial area on January 1st, according to Mr. T. R. Dester of the Associated British Railways.

"From January 1, 1936 the penny-a-mile third class and three-halfpence-a-mile first class rates will apply to any journey in the area no matter how short, and such tickets will carry also the full month's availability," Mr. Dester said. "The area covered by the experiment is the main line from Newport through Cardiff. Neath, Swansea and Llanelly to Carmarthen, all branches to the south of this line and north as far as Abergavenny, Pontsticill Junction Merthyr), Colbren (near Tunction Llandilo, including the Eastern and Western Valleys, the Rhondda Valley and the Lynvi and Ogmore Valleys.

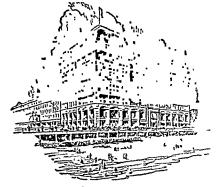

"Hundreds of stations will be affected by the experiment."

these waters, was caught with rod and rect two and one-half nules southerst of St David's Light, Bermuda, by Mrs Stanley W Smith of Pittsburgh on January 22nd

Mrs Smith pulled in her fish on a twentyfour thread line, nine ounce tip, using cut but Bermuda anglers hail the catch as proof of the sporting possibilities of the island waters

"Since the pioneering days of Bermuda fishing, less than a year ago, rod and reel men have been bringing in more and more varieties," F. G. Rounthwaite, general manager of the Bermuda Development Company, Ltd, points out 'Marlin is one species that we knew were present in these waters and Mrs. Smith's catch definitely proves it. There is little doubt in our minds that this catch heralds the final stage of development of these waters as among the foremost in the deep sea anglers' guide."

Only recently, Mr Rounthwaite brought to Bermuda two fishing captains experienced in deep sea angling, Captain Charles Christianson, who piloted Mrs Smith's boat, and Captain Harold Driscoll, whose thirty-six foot trawler is famous along the New Jersey and Long Island coasts

Wahoo are to be found in increasing abundance in Bermuda waters, Mr Rounthwaite

said, adding that regularly large catches are being made of Tuna, Amberjack, Barracuda, Yellow-tail and Mackerel, Mr. Rounthwaite believes that deep sea anglers will be increasingly enthusiastic about the islands with Mrs. Smith's Marlin catch.

Getting Set-to Go!

There is more than one way to board a boat, select a cruise, take a train, and in general to plan your vacation—but there is less choice in such preparations as will assure complete and perfect enjoyment.

The first vacation question naturally is. "how much can we afford to spend"-or per-

haps, "where shall we go?"

With these definitely settled, there follows any number of other questions that require the attention of the "family" board of directors. Such as—

"How long can we stay away?"

"What can we see and do where we are going?"

"What clothing will we need, etc."

And finally-

"How shall we travel?"

The Travel and Hotels section of your Journal, endcavors through advertisements and reading matter to post you on exceptionally fine hotels, transportation facilities, prospective cruises, transportation, and other things pertinent to vacation planning.

In addition you may have all the further help you require by contacting the Travel Department of the JOURNAL, which is equipped to not only give information but to assist as well in procuring the best accommodations at hotels and arranging the best transportation. All this service is free to readers and subscribers to the JOURNAL without the annoyance of solicitors or inconvenience of time used that you can ill afford to spare.

If you wish—specify the date your vacation starts, the time you wish to spend away, how much you want to defray for transportation, and this department will suggest several ways of getting the most for your "vacation dollar."

Travel Brevities

Among the guests recently seen at the St. George Hotel in Bermuda, was Dr. Edgar Kahn of Michigan.

Passengers sailing on Furness Bermuda Line steamers during the past few weeks included Dr. and Mrs. V. Ray of Cincinnati.

Maintain Mineral Alkali Balance

WITH

KALAK

Hypertonic—Alkaline—Carbonated—Not Laxative

The years of experience with physicians who have used Kałak show that the use of a formula containing calcium, magnesium, sodium and potassium salts represents a correctly balanced solution. This is Kalak which, as such, aids in maintaining a balanced base reserve.

How Alkaline Is Kalak?

One liter of Kalak requires more than 700 cc. N/10 HC1 for neutralization of bases present as bicarbonates. Kalak is capable of neutralizing approximately three-quarters its volume of decinormal hydrochloric acid.

MILK

as a potential agent in Dermatoses

The relation of calcium deficiency to dermatological conditions has only lately been investigated. As yet, calcium therapy has not been demonstrated as specific in skin disorders. But it has been successfully employed many times. Brilliant results occur in certain cases of eczema and moist, itching dermatoses. As an agent for calcium therapy, milk merits consideration because of its rich calcium content. It would seem by inference, that milk is a practical means to increase calcium intake, thus helping to maintain the health of the skin.

*Reference: Calcium Metabolism and Calcium Therapy.

MEL THE STATE OF NEW YORK

A PLUS

In Nutritional Content

△ DDING-tastelessly-to milk the natural Vitamin D of Cod Liver Oil assures proper utilization of the high calcium content of the milk and therefore helps build stronger bones and teeth

It is a sum in simple nutrition—a logical, convenient and wholesome blend

Every quart of Vitex* Vitamin D Milk has a potency of 400 U.S.P. Vitamin D units-the Vitamin D equivalent of 11/4 teaspoonsful of U.S.P. Cod Liver Oil,

*Vitamin D Concentrate developed in the laboratories of and controlled by Columbia University.

MAINTAIN MINERAL ALKALI BALANCE

WITH

LAK

Hypertonic—Alkaline—Carbonated—Not Laxative

The years of experience with physicians who have used Kalak show that the use of a formula containing calcium, magnesium, sodium and potassium salts represents a correctly balanced solution. This is Kalak which, as such, aids in maintaining a balanced base reserve.

How Alkaline Is Kalak?

One liter of Kalak requires more than 700 cc. N/10 HC1 for neutralization of bases present as bicarbonates. Kalak is capable of neutralizing approximately three-quarters its volume of decinormal hydrochloric acid.

More satisfactory results with an arsphenamine plus a heavy metal

ADEQUATE ARSPHENAMINE THERAPY, supplemented with a heavy metal preparation, offers the surest means of arresting and curing syphilis. Continuous treatment is important if neuro-recurrences are to be prevented and maximum curative results obtained. This treatment should consist of a sufficient number of doses of the arsenical plus an adequate number of injections of the heavy metal.

Neoarsphenamine and Iodobismitol with Saligenin—two products by Squibb—are of distinct advantage in the treatment of syphilis. Iodobismitol with Saligenin is a propylene glycol solution containing 6% sodium iodobismuthite, 12% sodium iodide and 4% saligenin (a local anesthetic). It provides bismuth in anionic (electro negative) form.

Iodobismitol with Saligenin is rapidly and completely absorbed and slowly excreted, thus providing a relatively prolonged bismuth effect. Repeated injections are well tolerated in both early and late syphilis.

Neoarsphenamine Squibb is readily and rapidly soluble and possesses uniformly high spirocheticidal power and low toxicity. Arsphenamine and Sulpharsphenamine are also available under the Squibb label.

Lobar Pneumonia and Serum Therapy

FREDERICK T. LORD, M.D.

Clinical Professor of Medicine, Emeritus, Harvard Medical School; member of the Board of Consultation, Massachusetts General Hospital; member of the Massachusetts Advisory Committee on Pneumonia.

RODERICK HEFFRON, M.D.

Field Director, Pneumonia Study and Service, Massachusetts Department of Public Health.

This handbook discusses fully the use of antipneumococcic serum in the treatment of lobar pneumonia, with special attention to the clinical diagnosis of the disease, the selection of cases for serum treatment, identification of pneumococcus type, technique of administering the serum, precautions to be observed, possible reactions and their treatment, and the results of serum therapy.

Recent experience has shown that serum can be given advantageously by general practitioners in the home, under the conditions set forth in this book. In treated cases there has been a reduction from the usual 25 per cent mortality to 11 per cent in Type I cases and from 41 per cent to 27 per cent in Type II cases.

The handbook is based upon experience with hundreds of cases over a period of several years.

for more than 4 years—

Pernicious Anemia has been adequately and economically treated with

PARENTERAL LIVER EXTRACTS Sectorile

Potent, Clinically Tested Extracts provide for

- Intensive therapy during the period of relapse with a minimum
 of inconvenience (11, reduced volume and a small number of
 injections) to the patient
- Rapid hematopoietic response and general improvement of all symptoms
- The intensive treatment of cases with marked neurological changes those having complications and those advanced in years—all of which require more than normal amounts of the antianemic substance

Authorities on the treatment of pernicious anemia are agreed that the injection of liver extract derived from a certain amount of fresh liver gives an effect equivalent to 30 to 60 times that amount administered orally

LEDERLE'S latest contribution to the effective and economical treatment of Pernicious Anemia is

1 cc CONCENTRATED SOLUTION LIVER EXTRACT Lederle
Supplied only 11 boxes of three 1 cc vials—each vial containing antianemic substance obtained from 100 grams of liver

PROTECTING THE EXPECTANT MOTHER

ORMAL PREGNANCY has its disturbances. During the first half of pregnancy the woman's metabolic rate is not changed. After the fourth month it gradually increases to 23% above her norm. Caloric increase in the diet is thus necessary after the fourth month.

But vomiting of pregnancy interferes! The condition is looked upon today as a disturbance in carbohydrate metabolism. Upon this assumption is based the present-day treatment by carbohydrate diet. The early introduction of small carbohydrate meals at 3 hour intervals helps prevent this disturbance. Karo added to foods and fluids prevents glycogen depletion and ketosis.

The enlarging of the uterus further produces reflex vomiting and unless carbohydrate is taken throughout the day to maintain the blood sugar at a high level, ketosis results. This aggravates the vomiting, frequently beyond control, because of the inability of the damaged liver in pregnancy to resist ketosis. Karo helps provide the expectant mother with readily assimilated sugars preventive of ketosis. Karo consists of dextrins, maltose and dextrose (with a small percentage of sucrose added for flavor), not readily fermentable, rapidly absorbed and effectively utilized.

Corn Products Consulting Service for Physicians is available for further clinical information regarding Karo. Please Address: Corn Products Sales Company, Dept. M.2, 17 Battery Place, New York City.

Foundation and Superstructure

"Word-of-mouth" advertising is the most powerful advertising medium in the world. You recommend a book, a play, a trip, a hotel, a medical preparation, a sanitarium, a hospital, to another. He passes the word along, others do the same, and so good-will is built up, and reputation, and success.

But printed advertising is the foundation of word-of-mouth advertising—setting forth quality and achievements in detail and supporting the oral recommendation. Both forms are essential, like foundation and superstructure of a building.

Because both are so closely cemented, the foundation must be firm, solid, laid true and strong. Constant effort is made to keep questionable material out of the foundation—"printed advertising" in this JOURNAL, so that the superstructure—"word-of-mouth recommendations" will be credible.

The test of an advertiser, and your assurance of his worth, is the continued appearance of his printed message in the New York STATE JOURNAL OF MEDICINE.

DON'T JUDGE THE RANGE OF THIS OFFICE-PORTABLE X-RAY UNIT BY ITS SIZE

pecause the G-E Model "F" Office-Portable X-Ray Unit seems to you so extremely small in size, and its low price places it easily within your means, don't make the mistake of overlooking its practical diagnostic range and ability to produce radiographs of fine quality.

The principle of complete oil-immersion of both the high-voltage transformer and the x-ray tube in a single, sealed container accounts for this unusual compactness and high efficiency.

Moreover, it makes the outfit absolutely shock proof under

WHEN AUTOMOBILES LOOKED LIKE THIS

S.M.A. was FIRST made ANTIRACHITIC

Ever since 1914, S. M. A. has contained enough Vitamin D activity to prevent rickets and spasmophilia

Vitamin D is one important factor in infant nutrition but it is not new to the many thou sands of physicians who have prescribed S M A (containing Vitamin D) during the past twenty one years

Vitamin D is only one of the many features of S M A. The fundamental idea behind S M A.

is that breast milk from the normal, completely nourished mother is the ideal food for the human infant. That is why S M A is made to resemble breast milk in percentages of carbo

hydrate, protein fat and total salts (ash) content and why even the chemical and physical constants of the fat in S M A are like those of breast milk fat

Physicians from coast to coast, in city, town, and village, are prescribing SMA today—not for any one of its many desirable features, but

because all of them combine to pro duce excellent nutritional results more simply and more quickly.

May we send literature and samples?

THEOCALCIN

In angina pectoris Theocalcin is often employed for a prolonged vasodilator action on the coronary vessels, or to quard against constriction and reduce the frequency and severity of painful attacks. Treatment is best begun with 2 or 3 tablets several times a day; then the improvement may be continued with smaller doses

THEOCALCIN (theobromine-calcium salicylate) Council Accepted

Available in 7½ grain tablets and as a Powder

An open letter to the Thysicians of New York State—

Topical applications of a mildly stimulating medicinal antiseptic and lavage of the masal mucosa has always been indicated in treating sinusitis and other infections of the masal tract.

Successful prescription by physicians everywhere for treating these ailments gives convincing testimony that NICHOLS NASAL SYPHON is safe and a scientifically principled device for proper irrigation and drainage of the nasal cavity and accessory sinuses.

It operates on the scientific principle of SYPHONAGE, which is suction or negative pressure. The prepared solution enters one nostril and is drawn from the other after thoroughly flushing the entire nasal structure. The flow is under perfect control with the automatic shut-off and the notched nozzles prevent flooding of the nasal passeges. The operation is so simple a child may use the syphon with perfect safety.

We find this form of therapy is steadily gaining more adherents as its modus operandi is being better appreciated, because a nasal tract that is thoroughly cleansed, routinely tends to resist the infectious inroads of attack and place the nasal mucosa in a condition to throw off the disturbance.

If you have not tried this method of treatment we urge you to do so. See that your patients get a NICHOLS Nasal Syphon on your prescription—and be convinced. We guarantee satisfaction. Results will prove gratifying to you—and to the patient.

Write for special offer with money back guarantee.

A delicious refreshing breakfast fruit juice — nothing added but the water necessary in the making—ideal for children and adults — acts to aid regularity. At all grocers. Full qt. 25c.

Watch the Food Element

Regulations regarding food products are becoming more stringent with the advance of federal, state, and municipal standards. In both enactment and enforcement of food regulations, physicians have taken a rightful part. But there is still inferior products foisted upon the public, and that ever-dangerous handling of unpacked and questionable quality foods. Physicians might, for the protection of patients, recommend foods they know are clean and come from accepted sources, and so protect their patients.

PURE JUICE of Big Red-Ripe Whole Tomatoes

Vine-ripened tomatoes of exceptional flavor and deep red color ... carefully washed, peeled and cored ... are used in making Kemp's Sun-Rayed Pure Tomato Juice. Exclusive process (U. S. Pat. 1746657) retains all possible food values. A pure undiluted juice which you can safely rec-

ommend to your patients. Write for Steenbock Report on Feeding Tests, J-36.

KNOX SPARKLING GELATINE

Cest* shows~

KNOX GELATINE Greatly Reduces Curd Tension of Milk

A coagulent was added to Grade A milk. The curd tension was 60.4.

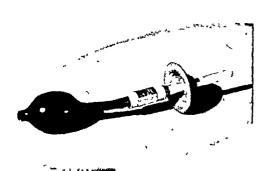

One percent of Knox Gelatine (plain) was added to the same grade of milk. The reading was 28.2, or a curd tension reduction of more than 50%.

Knox Gelatine is an exceptionally pure product. It is of the same neutrality as certified milk and, like milk, has colloidal properties. In difficult infant feeding cases, one envelope (¼ of a package) may be mixed with the day's supply of food.

As reported before the American Chemical Society, June, 1935.

In view of the growing concern that is being manifested both by the general public and by the maedical profession in regard to the risks of arsenceal poisoning from incidental sources, it seemed to me that the story of our recent investigations in this field might be worth recording

a few instances given temporary relief, treatment of various kinds, which had in some had long instories of symptomatic already been examined elsewhere, and Many of these patients had disturbances more or less vague but persistent digestive pairment of vision, muscular atrophy, and becessuesias and paresthesias, tremors, imrestations, other disturbances, such as hytound, in addition to the cutaneous manipatients more carefully, we frequently When we came to study these ing of hair, and abnormalities of pigmenparticularly of the palms and soles, tallaccompanied by thickening of the skincuronic poisoning by arsenic eruptions scuted skin conditions suggestive of Chinic, an increasing number who prement of Dermatology of the Vanderbilt among patients admitted to the Depart-Some years ago we began to notice, this field might be worth recording

practed to make their condition worse.

Among these latter especially, we discovered some patients with a history of arsenical medication, and others who, though unavase of having had arsenic mit have the worst long periods. When we found that the blood and urms of these patients contributed in the proof of the proo

and in a considerable number, had ap-

although in the majority little or none,

for arsenic by means of the Justus-Brünauer-Osborne method revealed typical granules of arsenic trisulphide. Some of these findings have been reported in detail in the paper of Cannon and Karelitz² on "Vitiligo from Arsphenamine Dermatitis and from Arsenic of Unknown Origin."

The major problems immediately confronting us were: Where did this arsenic come from? Was it responsible for the patients' symptoms, or was it merely an

incidental finding?

To the first of these questions a partial answer was already at hand. It was just about this time that public attention was being drawn to the dangers of poisoning from fruits and vegetables sprayed with compounds of lead and arsenic. In 1925 the British health authorities had threatened an embargo on American fruits whose spray residue contained more than 1/100 of a grain of arsenic trioxide per pound of fruit. This limitation had been in force in England for over twenty years, ever since a British Royal Commission concluded its investigation of the famous Manchester epidemic of 1900, in which six thousand persons were poisoned, seventy of them fatally, from beer contaminated with arsenic.

Meanwhile, in the United States, the problem of insect control had grown to The apple is formidable proportions. said to have five hundred species of insects feeding upon it, and virtually every cultivated crop has its scores and, in some cases, hundreds of different kinds of insect enemies. To combat their ravages, the use of insecticides has increased by The United States leaps and bounds. Census Bureau estimated the total manufacture of arsenates in this country for 1929 at \$5,537,951, of which lead arsenate alone, the standard arsenical insecticide of most universal application, accounted for \$3,304,351. This represents an increase of nearly three hundred per cent in the use of lead arsenate during the period from 1919 to 1929, and an increase of nearly one thousand per cent for calcium arsenate over the same period. ures for 1933 indicate some falling off in production since 1929, due probably to economic conditions. Attempts of the Food and Drug Administration to regulate more stringently the arsenic residues on sprayed fruits and vegetables have brought to the fore the question as to how much arsenic people might be taking into the system from other sources as well. Within the past few years not only scientific publications but popular magazines, books, newspapers, and radio have brought to the notice of the general public the risks of poisoning from arsenic contained in various foods, candies, tobaccos, in cosmetics, in paints, wall-paper, and dyed clothing—to cite only a few common examples.

Most of these have been known to toxicologists for generations, but chiefly as sources of acute poisonings, especially fatal ones, which come up for medicolegal investigation. In such cases, particularly where foods are involved, the arsenic is more often than not added, either with homicidal intent, or by accident or gross negligence. The significance of the present cases lay in the possibility that large numbers of people, exposed continuously to small amounts of arsenic from a multitude of everyday sources, might be slowly but none the less surely poisoned through its cumulative effects; and that this largescale poisoning—if it existed, would be all the more dangerous for being derived from sources for the most part perfectly legitimate in themselves.

Of course we could not conclude from our laboratory findings alone that these patients were suffering from arsenical poisoning. It was necessary first to inquire much more carefully into the case histories for other possible origins of their symptoms; to eliminate suspected substances from diet and surroundings; and to watch the results of treatment, especially treatment designed to hasten the excretion of arsenic.

As a result of these measures, there gradually accumulated a considerable number of cases in which the symptoms were quite definitely traced to poisoning from arsenicals; side by side with these were others originally thought to be cases of arsenical poisoning but eventually shown to be due to other causes. In still other cases, there was some evidence that arsenic was at least a contributory factor, but a final decision must await the solution of additional questions. It was hoped that the inclusion of all types of cases in our account might help to stimulate interest in both the possibilities and the short-

TABLE I.

Case 11. H.G.T., well-nourished and healthy appearing young woman of twenty-two years, consulted me on November 29, 1930, for loss of hair dating from an attack of grip and nervous collapse four years before. The hair was quite thin over the scalp. There was no dandruff, nor were there any visible skin lesions. Blood count and urinalysis were normal, and the blood Wassermann was negative.

The patient volunteered the information that her hair had been coming out in much larger quantities since the middle of July, during a sojourn in Switzerland in company with her father and mother. While living at a hotel, all three had been seized with nausea, vomiting, abdominal cramps, and diarrhea, accompanied by general weakness, vertigo, and itching of the skin. In addition, she herself had had a sore throat and a universal rash, followed by peeling of the skin over the entire body. It was at this time that she had noticed her hair coming out more freely than before. Simultaneously, guests in other hotels of this and neighboring towns were reported to be suffering from similar symptoms, and the trouble was diagnosed by local physicians as acute arsenical poisoning caused by eating fruits and vegetables which had been sprayed with arsenical compounds.

Since that time the patient has continued to suffer from time to time attacks similar to the first one, although less severe. She is also troubled with burning sensations in the soles and palms and here and there over

the skin. Her physician had reported her liver considerably enlarged.

These recurrences have sometimes coincided with the ingestion of fruit found to have been sprayed with arsenical compounds, and have subsided when that fruit was eliminated from the diet. The patient explained that for the past two summers, while vacationing in Maine, in a locality where no arsenical sprays were used on the fruits and vegetables, all three members of the family felt perfectly well. On their return to New York last fall, they stopped at a friend's house in Connecticut, where after having eaten two washed and baked home-grown apples apiece for supper at six P. M., they developed acute symptoms similar to those of the original attack. The patient's father, who had in addition eaten a washed raw apple before going to bed, became violently ill at five A. M., and the patient and her mother were stricken two and one-half hours later. It was then learned that the apples had been sprayed four times during that season with an arsenical compound. On two other occasions, within a month after returning to New York City after a vacation during which only unsprayed fruits and vegetables were eaten, the patient had suffered recurrences of gastrointestinal symptoms, including slate-colored stools, and the other members of the family were similarly affected.

Treatment for the condition was instituted in the form of sodium and calcium thiosulphate in alternating courses, both intravenously and by mouth. The patient's response was soon evidenced by a regrowth of hair and by marked improvement in her general condition. The amounts of arsenic found in the blood may be seen from Table II, in which are included also the blood arsenic figures for the other two members of the family, father and mother of the patient in Case 11.

Case 12. Dr. A.S.T., physician, sixty-two years of age, father of H.G.T., consulted me on March 10, 1931, complaining of itching of the skin, with frequent attacks of hives, and occasional nausea and vomiting. He also complained of fatigue, general weakness, and vertigo. The general physical examination was negative, except that the liver was palpable. The blood count was normal, and the blood Wassermann negative. The patient reported having been operated upon for duodenal ulcer five years before, but had been perfectly well since that time until the previous July, when his present trouble had appeared while he was in Switzerland with his wife and daughter. At this primary acute attack he had vomited some blood. Recurrences of the gastrointestinal and other symptoms (without bleeding)

had had an eczema limited to the face (especially the forehead) and the fingers for the past three years, but that it was not until two weeks ago that the process had spread to other parts of the body. Upon examination, he presented a profuse erythematosquamous eruption, with some scaling, on the trunk and extremities, including the hands and the feet between the toes. The scalp and forehead were covered with fine dry yellowish scales. There was marked keratosis of the palms, with extensive fissuring; the soles were similarly involved but the process there was less advanced. Two successive examinations for tinea were negative. The Wassermann and Kahn tests were negative. Upon being questioned the patient admitted that he had begun taking Fowler's solution (three to ten drops) two months before, and had continued until ten

A blood specimen taken on the day of admission was found to contain .163 mg. of arsenic, and a urine specimen of a few days later showed .212 mg. arsenic. The patient was given twelve intravenous injections of sodium thiosulphate in the next five weeks. During this time the blood arsenic steadily declined, three successive analyses being reported as follows: May 13.11 mg. arsenic; May 16 .04 mg. arsenic; May 28 .02 mg.

By June 11 the patient's skin was almost clear, except for the hyperkeratosis of the palms and soles. He then stopped treatment for three months and returned at the end of that time with a vesicular rash on the dorsum of the fingers and a recurrent dermatitis of the face. At this time the blood arsenic was found to be .621, the urine arsenic .895 mg.

It is of course uncertain whether the original dermatitis was due to arsenic, but it is interesting to note that arsenical medication, instead of ameliorating the condition, caused it to spread; that sodium thiosulphate therapy was followed by a decided improvement coupled with a progressive dimnution of the blood arsenic; and that cessation of treatment for several months was followed by a marked rise in arsenic in the blood and urine, simultaneously with a recurrence of the skin manifestations. The patient dis-claimed any further arsenical medication, and other sources for the arsenic could not be found.

A few additional cases of dermatitis have been selected for brief résumés, as they illustrate fairly well the problems encountered:

Case 2. B.O.C., sixty-four years, male, artist, consulted me on March 3, 1930, for an intensely itching eczema of the back,

shoulders, and extremities, of three weeks' duration. There were numerous red, scaling, crusted and excoriated areas, from dime- to palm-sized, mostly on the flexures, Wassermann reaction was negative; examination for tinea was negative; blood chemistry was normal; and the blood arsenic was .115 mg.

The patient's general health had been excellent. He spends his time painting in a studio on his farm. He had never taken arsenic in any form. The rash cleared up under sodium thiosulphate medication, but recurred a few months later. At this time the blood arsenic was found to be .952 mg. Sodium thiosulphate was again tried, both by injection and by mouth, and the skin became normal. The blood arsenic taken after all manifestations had disappeared,

was reported 0.000.

Case 4. P.B.P., male, fifty-five years, fruit-grower, came to me on October 3, 1933 with an acute generalized dermatitis of one month's duration, most marked on the face and extremities. The patient had had a recurring vesicular dermatitis of the face and hands for fifteen years, but during the past month the condition had become almost universal. He had obtained no relief from soothing baths, lotions, ointments, and two x-ray treatments. A tentative diagnosis of fungus infection was made, but repeated examinations for fungi were negative, and the condition grew worse under corresponding treatment. Skin tests done with the ingredients contained in the various lotions and ointments the patient had applied also gave negative results. The blood Wassermann was negative.

Meanwhile I learned that the patient, although resident in New York, had a large apple farm in Virginia, where he raised fruit for export. He sprayed the apples four times a year with an arsenical preparation, and admitted that his exacerbations and recurrences coincided with his visits to the farm. His blood was now taken for arsenic and found to contain .17 mg. Rapid improvement followed treatment with calcium and sodium thiosulphate, with olive oil used locally. By December 29 his skin was entirely clear, and his blood at that time

showed .05 mg. arsenic.

Case 5. W.D.T., male, fifty-six years, jewelry salesman, consulted me on September 30, 1930, for a universal dermatitis of six months' duration, accompanied by intense itching, insomnia, nervousness, and loss of The condition had begun on the thighs and groins as a red rash, gradually spreading all over the body, until now there was universal redness, scaling, thickening and excoriation. The blood chemistry and the urine were normal, the Wassermann was

Means Means qà scy Esuout to ing yould have ni tasiteq syl unt of arsenic dns of or App. viris root in any even when she had ot one are to beat irritant, as the later · н илиси шау гиен тесит would suffice to start a tolerance, when almost arsenic closely approachhaps already accumulated two preceding ones, the ther words, in cases such rely the immediate excittinal cause, may not have he shaving cream, instead ing to speculate whether in

ing preparation, and that it had spread the next day to the entire body. The patient avoided this shaving preparation, and the dermatitis subsided in about three weeks, following the use of cornstarch and oatmeal baths, and soothing ointments. The psorrisis did not improve

A little later this patient developed manifestations more strongly suggestive of arsenic On February 26, 1931, about three months after his original dermatitis had cleared up, intradermal tests were performed with neo, old and silver arspheniume Seven days afterwards, these showed a marked positive reaction, consisting of a nodule on the site of each injection, surrounded, in the case of old arsphenamine, by an area of dermatitis seven cm in diam-These reactions involuted slowly over a period of about two months, and four blood specimens taken during this time showed arsenic from 04 mg to 21 mg A few days after the latter figure was ob tained, the patient appeared with a flareup of dermatitis on the site of the intradermal test with old arsphenamine This local dermatitis spread until it covered the entire external aspect of the arm and was intensely pruritic. It involuted in about four weeks, leaving a small nodule on the site of the injection. A blood sample taken while this local recurrence was at its height, showed 76 mg arsenic, more than treble that of any previous figure

It is interesting to speculate whether in this instance the shaving cream, instead of being the original cause, may not have constituted merely the immediate exciting factor In other words, in cases such as this and the two preceding ones, the patient has perhaps already accumulated in his organism arsenic closely approaching his limit of tolerance, when almost any local irritant would suffice to start a general reaction, which may then recur even without the local irritant, as the later attacks of Case 34 occurred-if we are to credit her testimony-even when she had not been in contact with orris root in any form It is of course hardly to be supposed that the minute amount of arsenic introduced into the skin of the patient in Case 51 in the intradermal test would have any effect upon the arsenic content of the blood, unless by the provoking of a general allergic reaction, arsenic already accumulated in the skin or in internal organs should be set free into the blood stream For other cases and discussion of arsenic in connection with polyvalent sensitiza-

tion, the reader is referred to the paper of Cannon and Karehtz³ on "Intradermal Tests in Relation to Arsphenamine Dermatitis"

We would now consider briefly some of the other conditions besides dermatitis for which the patients in this series first came to our attention

Alopecia and falling hair (18 cases) addition to those in which falling hair or partial alopecia appeared as a sequel to an arsenical dermatitis, such as Case 11, there was one (Case 17), a woman of forty vers, in whom loss of hair was coupled with frequent nausea, a marked garlic odor of the perspiration, and symptoms of peri-pheral neuritis. This patient was pale, easily fatigued, and nervous. Her general physical examination was negative hemoglobin was a little low, but the blood count, blood chemistry and urinalysis were normal Blood arsenic was 218 mg After a few weeks of sodium thiosulphate medication, the blood arsenic had risen to 204 mg, to drop in a few weeks more to 046 mg During this time the patient's improvement was pronounced. Her hair was coming in well, the garlic odor had disappeared, and she felt much better generally hair rinse used by this patient had been analyzed for arsenic in the beginning, and was found to contain 0025 mg arsenic She had never taken (two packages) arsenic

There were also in this group several cases of premiture baldness, of unknown origin but associated with considerable amounts of arsenic in the blood, and there were five cases of alopecia areata blood arsenic of the patients with alopecia areata taken at the first visit, averaged 814 mg, or nearly twice that of the average for the entire group. Two of these patients given sodium thiosulphate, responded with a regrowth of hair. A third who had an extensive vitiligo in addition to the alopecia failed to respond to treat-The two remaining patients did not return for treatment None of these patients had ever taken arsenic medicinally, and questioning failed to reveal any other source, with one possible exception the alopecia areata patient (Case 7) who had the highest amount of arsenic in the blood (185 mg on admission) was a manufacturer of cosmetics who was in his laboratory daily, supervising the work He denied direct contact with arsenicals, but opportunities for the indirect absorption of small amounts would be manifold, as in the case of the physician

Keratosis of the palms and soles (16 cases) Keratosis of the palms and soles,

Skin tests with the bath salts gave positive reactions. All remedies directed toward the elimination of arsenic were now stopped, and the patient was given a tar ointment, soothing baths, and carbon arc light. After ten light exposures his skin had become practically normal and he was free from itching.

Case 33. Occupational dermatitis from orange peel, lemon peel and bay rum, originally attributed to arsenic. Miss B., fiftyfive years of age, masseuse, came to me on June 23, 1933 with a history of repeated attacks of an acute dermatitis involving the face, neck, and upper extremities. A blood specimen showed .12 mg. arsenic. more specimens taken at six-week intervals, after sodium thiosulphate medication, showed .29 mg. and .054 mg. respectively. Neither fluctuations in blood arsenic, nor sodium thiosulphate therapy had any effect upon the dermatitis. On the other hand, the patient's skin gave strongly positive reactions to orange peel, lemon peel, bay rum, potassium dichromate, salicylic acid, and tincture of cantharides. The first three of these ingredients she had been using in her work. When contact with these irritants was removed, even though treatment directed toward the elimination of arsenic was discontinued, the skin gradually cleared.

Case 85. Dermatitis from hair dye, with presence of arsenic in the blood. Mrs. C.P., a generally healthy woman of fifty years, consulted me on December 5, 1933 for a dermatitis of the scalp, right temple and around the hair lines. Although arsenic was present in the blood in amounts of .195 mg. and .30 mg., on two occasions, the dermatitis was traced to the use of a henna hair dye, and disappeared after removal of the dye and appropriate treatment.

If the four preceding cases offer fairly conclusive evidence of being due to causes other than arsenic, the following three illustrate the type of case in which the evidence is so conflicting that arsenic can neither be incriminated nor wholly absolved without further observation:

Case 34. Mrs. L.Y., aged forty-eight years, consulted me on November 13, 1930, for a dermatitis of the forearms and axillae which had been present at intervals for one year. The present outbreak had begun three weeks before, and was attended with increasing itching. The dermatitis consisted of numerous dimeto palm-sized red, raised oozing, crusted and scaling areas, with considerable thickening of the skin in front of the elbows. There were also a few similar spots on the lower legs and thighs.

The blood chemistry and urinalysis were normal. The blood Wassermann was negative. Repeated examinations for fungi were negative. The blood arsenic was 1.1 mg. Of the numerous skin tests performed with foods and external irritants, the patient repeatedly gave a strong positive reaction to orris root. Removal of the orris root (used in talcum powder) and treatment with x-rays, supplemented by local soothing applications, caused the condition to clear up for the time being. However, the patient subsequently reported several recurrences of the dermatitis although she insisted that she had not used orris root in the meantime. On the most recent of these occasions the blood was found to have .03 mg. arsenic.

Case 49. I.C., aged thirty-five years, former furrier, was admitted to the clinic on January 21, 1930, for a generalized exfoliative dermatitis following x-ray, Alpine light, and chrysarobin treatment for psoriasis. His blood arsenic on admission was .005 mg; urinary arsenic on the same 1.23 mg. He denied ever he arsenic, although as in oil there is the possibility have been given without edge. His former provide opportunities. As he injections of private physic

clinic, his com

and high

Case 51. Mr. G., aged sixty-four years, psoriasis patient, came to the clinic on September 22, 1930, for a dermatitis of ten days' duration, generalized except for the psoriatic areas on hands, back, and feet. The patient denied ever having received arsenical medication for his psoriasis. Wassermann tests of the blood and spinal fluid were both negative, although the patient admitted having syphilis twenty years before. A biopsy from the skin of the thigh showed .27 mg. arsenic, but the blood arsenic was reported 0.000. It was then learned that the dermatitis had originally appeared on the face after the patient had shaved for the second time with a well-known shav-

ing preparation, and that it had spread the next day to the entire body. The patient avoided this shaving preparation, and the dermatitis subsided in about three weeks, following the use of cornstarch and oatmeal baths, and soothing ontiments. The

psoriasis did not improve A little later this patient developed manifestations more strongly suggestive of arsenic On February 26, 1931, about three months after his original dermititis had cleared up, intradermal tests were performed with neo, old and silver arsphenamine Seven days afterwards, these showed a marked positive reaction, consisting of a nodule on the site of each injection, surrounded, in the case of old arsphenamine, by an area of dermatitis seven cm in diam-These reactions involuted slowly over a period of about two months, and four blood specimens taken during this time showed arsenic from 04 mg to 21 mg A few days after the latter figure was obtained, the patient appeared with a flareup of dermatitis on the site of the intradermal test with old arsphenamine This local dermatitis spread until it covered the entire external aspect of the arm, and was intensely pruritic It involuted in about four weeks, leaving a small nodule on the site of the injection. A blood sample taken while this local recurrence was at its height, showed 76 mg arsenic, more than treble that of any previous figure

It is interesting to speculate whether in this instance the shaving cream, instead of being the original cause, may not have constituted merely the immediate exciting factor In other words, in cases such as this and the two preceding ones, the patient has perhaps already accumulated in his organism arsenic closely approaching his limit of tolerance, when almost any local irritant would suffice to start a general reaction, which may then recur even without the local irritant, as the later attacks of Case 34 occurred-if we are to credit her testimony-even when she had not been in contact with orris root in any form It is of course hardly to be supposed that the minute amount of arsenic introduced into the skin of the patient in Case 51 in the intradermal test would have any effect upon the arsenic content of the blood, unless by the provoking of a general allergic reaction, arsenic already accumulated in the skin or in internal organs should be set free into the blood stream For other cases and discussion of arsenic in connection with polyvalent sensitization, the reader is referred to the paper of Cannon and Karelitz³ on "Intradermal Tests in Relation to Arsphenamine Dermatitis"

We would now consider briefly some of the other conditions besides dermatitis for which the patients in this series first came to our attention

Alopecia and falling hair (18 cases). In addition to those in which falling hair or partial alopecia appeared as a sequel to an arsenical derinitiis, such as Case 11, there wis one (Case 17), a woman of forty years, in whom loss of hair was coupled with frequent niuser, a marked garlic odor of the perspiration, and symptoms of peri-pheral neuritis. This patient was pale, easily fatigued, and nervous Her general physical examination was negative hemoglobin was a little low, but the blood count, blood chemistry and urinalysis were normal Blood arsenic was 218 mg After a few weeks of sodium thiosulphate medication, the blood arsenic had risen to 204 mg, to drop in a few weeks more to 046 During this time the patient's improvement was pronounced. Her hair was com ing in well, the garlic odor had disappeared, and she felt much better generally hair rinse used by this patient had been analyzed for arsenic in the beginning, and was found to contain 0025 mg arsenic (two packages). She had never taken arsenic

There were also in this group several cases of premature bildness, of unknown origin but associated with considerable amounts of arsenic in the blood, and three were five cases of alopecia areata. The blood arsenic of the patients with alopecia areata, taken at the first visit, averaged 814 mg, or nearly twice that of the average for the entire group. Two of these patients, given sodium thiosulphate sponded with a regrowth of hair A third who had an extensive vitiligo in addition to the alopecia, failed to respond to treat-The two remaining patients did not return for treatment None of these patients had ever taken arsenic medicinally, and questioning failed to reveal any other source, with one possible exception the alopecia areata patient (Case 7) who had the highest amount of arsenic in the blood (185 mg on admission) was a manufacturer of cosmetics who was in his laboratory daily, supervising the work. He denied direct contact with arsenicals, but opportunities for the indirect absorption of small amounts would be manifold, as in the case of the physician

Keratosis of the palms and soles (16 cases) Keratosis of the palms and soles,

besides appearing concomitantly with an arsenical dermatitis, may occur without other cutaneous manifestations, or it may be found together with abnormalities of pigmentation and of the nails, hair, and sweat glands. In one of our patients (Case 54) a colored woman forty-nine years of age, it was accompanied by a dry scaly lichenified dermatitis of the neck, axillary, cubital and popliteal folds and the sacral region, a brown-to-black pigmentation of the same areas, gradual loss of hair on the scalp, and complete loss of axillary and pubic hair. In four of the sixteen cases studied here, the keratosis was the only pathological condition in evidence. arsenic found in the blood of this group ranged from .000 to 4.45 mg., with an average of .589 mg. Treatment with sodiumor calcium-thiosulphate was more successful in the cases of keratosis accompanied by dermatitis than in the others. There was a larger proportion of patients in this group with a definite history of arsenical medication than in any other group studied.

Vitiligo (10 cases). The ten cases of vitiligo included in our series showed the lowest average figures for blood arsenic of any of the conditions studied, and the least response to treatment designed to hasten the elimination of arsenic. Yet some of the individual arsenic findings were surprisingly high: one case of almost universal vitiligo associated with an alopecia areata has already been mentioned; this patient showed a blood arsenic of 1.85 mg. on admission, which went down rapidly under sodium thiosulphate injections, but no clinical improvement was noted. Another vitiligo patient had 5.22 mg. arsenic in a specimen of skin taken on admission, but samples of blood and urine from this patient never showed more than .27 mg. arsenic, and his response to sodium thiosulphate therapy, as well as to oil of bergamot and Alpine light was slight. Inasmuch as the majority of these cases, together with three others, have already been embodied in a special report (Cannon and Karelitz), they will not be taken up in detail here.

Psoriasis (6 cases). Psoriasis, on the other hand, in so far as we may attach any significance to observations made on six cases—the only ones on which we have arsenic data—showed the highest average blood arsenic of any group, .933 mg. Individual blood specimens taken on admission ranged from .000 to 4.45 mg. The following case with the highest figure is of interest for other reasons as well:

Case 43. H.H., fifty-three-year-old house-wife, appeared with an eruption in the form of large red, scaling plaques with sharply defined borders, on arms, legs, and backs of the

hands; there were also some smooth yellowishpink patches on the chest and arms. The skin of the palms and soles was red and thickened. According to the patient's story, the eruption had appeared rather suddenly about seven months before, and a local physician had prescribed Fowler's solution, which she took for several weeks, then discontinued, then resumed about three weeks before admission. Meanwhile the eruption had spread and the backs of the fingers were puffy.

The blood specimen taken on the patient's admission to the clinic was reported by the laboratory to contain 4.45 mg. arsenic, one of the highest figures encountered. Sodium thiosulphate therapy was begun at once and continued for about seven weeks. During this time there was marked clinical improvement, and the blood arsenic by the end of the course was down to .09 mg. Treatment was then discontinued and the patient kept under observation. At the end of three months there appeared new psoriatic plaques over the body, and the palms and soles, which had become softer while the patient was under treatment, again showed plagues of hyperkeratosis. Local remedies were first tried for several months, without apparent benefit. Sodium thiosulphate therapy was then resumed and the patient had made both subjective and objective improvement when last seen, after six injections at weekly intervals. Blood arsenic figures are not available for this period, but the urine showed .44 mg. arsenic one week after the beginning of the last course of treatment, and a trace only, at the patient's last visit.

It is impossible to evaluate sodium thiosulphate therapy in most of the remaining cases, because x-rays, Alpine light, and local applications were also used and because the blood analyses made on these patients were not numerous enough to warrant conclusions.

One cannot help suspecting that some, at least, of the cases diagnosed as psoriasis are in reality forms of arsenical dermatitis. Oppenheim, investigating the case of a woman patient who had suffered from "psoriasis" for years, finally traced the trouble to wall paint in her dwelling. The paint was analyzed and shown to contain an enormous percentage of arsenic. Arsenic was present in the patient's urine, and her "psoriasis" cleared up rapidly under sodium thiosulphate injections, baths, and mild salves.

A psoriasiform dermatitis occurs occasionally as a reaction to arsphenamine injections, and may easily be mistaken for a true psoriasis. An arsenical dermatitis may also complicate an already existing psoriasis. It is safe to assume that the published literature contains by no means all the cases of psoriasis which have grown worse instead of better under the arsenical treatment so frequently prescribed. The development of skin cancer in psoriatic patients with his-

tories of arsenical medication will be taken up in connection with our epithelioma group. Acne (20 cases). The acne cases showed an average blood arsenic of .329 mg., with individual figures ranging from .000 to 1.79 mg. on admission. Here, as in the psoriasis group, sodium thiosulphate therapy was sup-

plemented by x-rays, Alpine light, and local applications, so that the cures obtained cannot be attributed to sodium thiosulphate

alone.

Cancer: - Epithelioma cases). Melanocarcinoma (1 case). All six patients who consulted me for epithelioma had considerable amounts of arsenic in the blood when first seen-minimum .10 mg., maximum 2.73 mg. None gave a definite history of having received arsenical medication, but one of the six, a physician, came in contact with arsenic in the course of his work. This patient (Case 8) and one other in the group had chronic skin eruptions; the remainder were free from symptoms usually associated with arsenical poisoning, except that two complained of fatigue and occa-

sional dizzy spells.

Ever since Hutchinson asserted in 1887 that long continued absorption of small quantities of arsenic may be followed by the formation of epithelial new growths, there has been a growing number of observations which appear to confirm this view. Dubreuilh⁵ in 1910 reported on arsenical keratosis in relation to cancer, and Ulimann⁶ has recently tabulated seventy-three cases, either published demonstrated, including six personal observations, in all of which epithelioma had developed after long continued exposure to arsenic. In most of these, the arsenic had been taken in the form of medication for psoriasis or other conditions, but five were from external contact with arsenicals in industry, and two followed long continued drinking of water contaminated with arsenic. Hamilton cites evidence of the arsenical nature of the keratoses, warts, and cancer of briquette makers, and thinks that the English cases of chinneysweeps' cancer and the epithelioma of English briquette makers can be traced to the arsenic in English coal.

None of the epitheliomas reported in the present study had developed on the site of any other visible skin lesion. The sites were as follows: in one patient, on the right chest; in another, on the right

cheek; in three, on the external nose, including two subsequent growths on one patient on different portions of the nose from the site of the original growth, the later growths corresponding to areas where the patient's glasses had rested; the sixth patient had an epithelioma at the inner canthus of the right eye and one on the right elbow. The procedure regularly followed was to remove the growth and irradiate the wound. In the three instances where sodium thiosulphate was given, it was followed by improvement in the patient's general condition and a reduction in the blood arsenic figure. Barring the one patient mentioned, no recurrences have been noted up to the time of writing. The rôle of arsenic

is of course problematical.

patient with melanocarcinoma, already discussed in the dermatitis group (Case 49) presented upon the dorsal surface of the right great toe a half-dollarsized ulceration which had appeared while he was being treated for his dermatitis. He also had at this time two melanotic spots about five mm, in diameter on the thenar eminence of the right palm, and a few others on the dorsum of each hand. A biopsy from the toe revealed melanocarcinoma. The toe was amputated but the patient died with metastases about eight months after admission. The blood arsenic was .006 mg. on admission and remained low throughout his stay, although the urinary arsenic on two occasions exceeded one mg., and a skin specimen from an area of dermatitis on the thigh showed 1.14 mg. arsenic. As the patient had already had six injections of sodium thiosulphate from a private physician before coming to the clinic, his comparatively low blood arsenic may have been due to recent elimination of the metal.

The amounts of arsenic found in the blood of a number of patients with miscellaneous diseases may be seen from Table Several of these cases merit brief discussion.

Case 15. Mrs. A.L., fifty-five years of age, came to me on November 8, 1928, complaining of painful mouth ulcers of a little over a year's duration. Over the mucous membrane of each cheek were two eroded areas one by one and one-half inches, covered with a thin grayish slough. The borders were red, and extending away from these were white linear areas. The soreness would disappear and recur but the white areas always remained. The general physical examination was negative. The blood chemistry was normal, the blood Wassermann negative. The blood arsenic was 1.61 mg.

The ulcers were at first attributed to phenolphthalein, as the patient had been taking phenolax for constipation. However, when this was stopped there was no improvement in the mouth condition, and skin tests with phenolphthalein were negative. In view of these facts and the high blood arsenic, the patient was then given sodium thiosulphate, both intravenously and by mouth. The ulceration healed, and had not recurred in three years observation. Two blood analyses following the sodium thiosulphate therapy showed 1.0 mg. and .148 mg. arsenic respectively.

In contrast to this case was another (Case 35) likewise with recurring blisters and sore areas of the gums and mucous membranes of the mouth. This patient, otherwise healthy, was a woman of forty-eight, who had a blood arsenic of .79 mg. She admitted taking laxatives and gave a strongly positive reaction to a skin test for phenolphthalein, and the lesions healed when the phenolphthalein laxatives were discontinued.

Among the more puzzling cases were two with symptoms suggestive of Raynaud's disease:

Case 24. Mrs. D.P., forty-three years of age, first consulted me on July 31, 1933 for a red vesicular, swollen and intensely pruritic condition of the feet and hands, extending to the knees and elbows. There was much oozing, crusting and excoriation. addition, the feet and hands were blue and cold, and several toes had been amputated on account of gangrene. A blood specimen taken at the first visit showed .285 mg. Under treatment with calcium thiosulphate, both by injection and by mouth, and local applications, the dermatitis cleared up entirely; but after treatment was discontinued for a few weeks, the trouble would recur. On one of these occasions a blood sample was found to contain .22 mg. arsenic. The Raynaud symptoms re-The patient denied ever having mained. taken arsenic.

Case 91. Mrs. L.M.G., aged thirty-eight years, came to me on February 16, 1935 for several pea-sized senile keratoses on her upper lip and forehead, acne of the nose and chin, and a condition of the hands and feet resembling Raynaud's disease. The latter had come on in the form of prickling and tingling sensations, alternating with

numbness. Under the influence of cold there was complete loss of sensation in the hands and feet and the parts would become alternately white and blue. Warmth produced redness and profuse perspiration. A change of two degrees in temperature sufficed to bring about a reaction.

The patient gave a history of having taken Fowler's solution for chorea at the age of twelve, and eight to ten injections of cacodylate of soda for a "run down condition" in 1925. Arsenic in the blood was reported by our laboratory to be .07 mg. After three intravenous injections of sodium thiosulphate, and sodium thiosulphate by mouth, the blood arsenic was .06 and the patient showed both subjective and objective improvement. She is still under treatment.

Both Osler and Pusey, among others, have considered arsenic poisoning in connection with erythromelalgia and the closely related Raynaud syndrome. Characteristic symptoms were noted in some of the severer cases of arsenic poisoning in the Manchester epidemic, in which they were associated with a peripheral neuritis. Putnam's collection⁸ of twenty-five cases of chronic poisoning from arsenical wallpaper and fabrics includes one with Raynaud-like symptoms which passed away after the removal of the arsenical paper. More recently Kraetzer³² has reported a case of Raynaud's disease associated with chronic retention of arsenic.

In addition to these more conspicuous symptoms already discussed-eruptions, falling hair, pigmentations (both melanoderma and jaundice), keratoses, polyneuritis, and occasionally the Raynaud syndrome—there are milder, premonitory symptoms often helpful in diagnosis in connection with other factors: (1) a garlic odor of breath or perspiration; (2) excessive salivation and sweating; (3) stomatitis (occasionally the sole symptom preceding a universal dermatitis); (4) generalized itching without objective symptoms, sometimes met with as the precursor of a dermatitis and of jaundice from liver impairment; (5) the "cold" involving sore throat, coryza and lacrimation, simulating the onset of influenza, but usually without a rise in temperature; (6) and the numbness, burning and tingling sensations which may herald a polyneuritis or a Raynaud syndrome.

There is also one class of reactions to arsenicals which deserves special mention, namely, those sometimes occurring after

intravenous administration of arsphenamines in the treatment of syphilis Most of these reactions occur either during or immediately following the injection, or at a short enough interval so that there is little difficulty in establishing the causal Chief among these are the relationship so-called nitritoid crises, and skin cruptions which range all the way from a striking but transitory erythematous rash to a severe exfoliative dermatitis, with generalized oozing, crusting, and grave constitutional symptoms Slower in onset are the symptoms of liver impairment, heralded by jaundice of various grades, and sometimes ending fatally in acute yellow atrophy Severe neuritis and nephritis are fortunately still rarer although mild manifestations of both are not uncommon after one or more courses of an arsphenamine preparation

These reactions do not properly constitute a part of the present study, except in so far as they must be reckoned with in fitting together the various links in the chain of evidence for or against arsenic, out of the patient's past history times a patient appears with a trouble some "eczema" that defies the usual treat-He denies ever having had syphilis. but admits that his present trouble started when he "broke out with a rash after a few arm injections from a private doctor ' His Wasserman is found to be strongly positive, an inquiry addressed to the doctor in question reveals that the patient received five or six intravenous injections of neoarsphenamine, but failed to return for the balance of the course "eczema" is an arsphenamine dermatitis which clears up under appropriate

treatment

Sources of Chronic Arsenical Poisoning

It will have been apparent from the foregoing instances that our efforts to determine the source of the arsenic revealed by our Inhoratory analyses were not uniformly successful. Simplest, of course were the cases in which there was a definite history of arsenical medication preceding the onset of the dermatosis. These cases were relatively few. More numerous were those in which the dermatosis antedated the medication, which had only aggravated it. Still more numerous, and

of greater significance for our purpose, were those cases in which the patient had not, to his knowledge, taken any preparation containing arseme

Inquiry into the occupations of this latter group revealed various opportunities for contact with arsenicals. One patient, it will be recalled, was a fruit-grower, another was a grocer, another a fruit peddler, all three had exceptional opportunities for handling and eating sprayed fruits, and in the one case, preparing the Three physicians arsenical sprays nurse, and a manufacturer of cosmetics handled arsenicals in the course of their work One patient, a candy-maker, was unable or unwilling to supply any direct information, but arsenic has been found quite regularly as an impurity in commercial glucose, used largely in the cheaper grades of candies It occurs in shellac used as a coating for candies, and in many of the colored papers used as wrappers for candies Two patients were furriers Furriers are exposed by the handling of skins treated with arsenical disinfectants and sometimes by the presence of arsenic in the dyes. Twelve case histories revealed contacts with paints, colored wall papers, and household insecticides. Of these patients, four were painters (house painters or sign painters), two were wife and daughter of a painter who kept his materials at home. two were artists, and one an interior In the three remaining instances either the original ailment or a recurrence had followed the repainting or repapering of the patient's apartment One of these, a dermatitis patient, reported that she was free from manifestations while away from home for two weeks, but immediately upon her return suffered a recurrence of her "eczema" This patient and several others reported that their itching was much more troublesome after the use of insecticides in their apartments. The artists and the interior decorator would of course have ample opportunities to come in contact with paints and dyed fabrics. Some artists have a habit of pointing the brush in their mouths

Arsenic in fabrics and wall-coverings Arsenical poisoning in industrial workers from paints, enamels, metals and their byproducts has long been a matter of common knowledge. It is less generally known, however, that arsenic present in colored wallpapers, wall-paints and hangings, and household objects may be toxic for the occupants of rooms containing such furnishings. Petren, after exhaustive study undertaken at the behest of the Swedish Government, came to the conclusion that both wallpaper and wallcontaining arsenic may cause poisoning in occupants of rooms, as may also dyed bed and mattress coverings, upholstery, curtains, stuffed birds, lampshades, and clothing. As for the United States, following an investigation of poisoning cases in Massachusetts around 1900, in which surprisingly large amounts of arsenic were found in wall-coverings, carpets, furs and fabrics, a state law was passed limiting the amount of arsenic to .01 grain per square yard for dress fabrics, and .1 grain per square yard for other materials. There is, however, no federal law regulating poisonous substances used in manufactured products, and so far as the author has been able to discover, Massachusetts is still the only state in the Union which places any legal limit on arsenic in wall-coverings and fabrics.

Many current writers, among them toxicologists of repute, dismiss this hazard with the comment that arsenical dyes are no longer used, having been supplanted by vegetable or aniline colors. But Kober¹⁰ admits that stockings, gloves, etc., dyed with aniline colors often do produce severe irritation of the skin on account of the presence of arsenic (used in flixing certain colors) which should not pass over into the finished product if the process is rightly carried out. There is furthermore the possibility of arsenic being carried along from the raw product into the finished goods, irrespective of the dye used, because of the use of arsenical sheep dips and the dusting of growing cotton with arsenical sprays. Myers and his co-workers11 report considerable amounts of arsenic both in cotton and in finished cotton goods, while analyses\s made by the United States Bureau of of hemistry12 since the passage of the Massalachusetts law have also disclosed excel sive amounts of arsenic in "entirely too on large a percentage of furs and dress good is on the market." One may well wonder whether we are not taking too much for granted in assuming that our colored fabrics are arsenic-free.

Arsenic in Foods. The experiences of three of our patients in eating sprayed fruit have already been described. Unfortunately in cases of suspected poisoning it is not always possible to identify the offending substance, even when circumstances point strongly to arsenic. In a series of cases communicated to me personally by Dr. George H. Roth¹³ of the Los Angeles County Department of Health, it was possible to trace the patients' symptoms to their source.

During the summer of 1933 physicians of Los Angeles and vicinity were called to attend a surprisingly large number of persons suffering from acute gastroenteritis, chiefly in the form of vomiting, diarrhea, and abdominal cramps. In some cases there was also fever up to 102° F.; in several there were bloody urine, stools, and/or vomitus, cold sweats, thready pulse, and great prostration. Thanks to an active local Department, these cases promptly investigated. Thirty in one locality were traced to a Sunday meal in which cole slaw was served to all. secured from the same lot from which the slaw was made, showed by analysis .354 grains of arsenic trioxide per pound, or more than thirty-five times the limit of safety fixed by the United States Government. One child from a neighboring town had been stricken with vomiting, cramps, diarrhea, and prostration after eating an unwashed and unpeeled pear. Three other children who had eaten washed pears of the same lot were not ill. Analysis of unwashed pears from this lot showed .538 grains of arsenic trioxide per pound, or nearly fifty-four times the limit of safety. In addition to cabbage and pears, arsenic was found also on celery, broccoli, and spinach from various markets in the vicin-One patient was seized with severe vomiting which lasted for several hours, after eating a single stalk of celery. An elderly woman whose supper had consisted entirely of boiled spinach was awakened early the next morning by vomiting, diarrhea, and cold sweats. Urine, feces, and vomitus from these and other cases investigated by the County Board of Health yielded arsenic in significant amounts. should be decidedly worth while to keep these patients under observation for evidences of chronic retention of arsenic.

In the above instances, cooperation of the physician with the County health authorities, and the energetic measures of

the latter, solved the immediate problem at its source The clinic patient, however, attending for his chronic ailment, is rarely if ever seen in the acute phase by the same physician, but careful questioning will often elicit a history of "bad stomach upsets after eating greens," or "Can't eat salads—they give me cramps" Not all the cases popularly reported as "ptomaine poisoning" are caused by the As in the California cases, ptomaines it is not unreasonable to suppose that for the comparatively few persons who happen to eat freely of one lot of funts or vegetables containing a spray residue high enough in arsenic content to cause acute manifestations, there must be many more who escape with symptoms too mild to enlist medical aid at the time, yet increasingly dangerous when the cause is not removed

This, unfortunately, is a hazard to which we are all exposed, sooner or later It is easy to dismiss the idea with the facetious comment of the trade journals that it would be necessary to eat three bushels of apples at a sitting in order to get a minimal dose of arsenic in the form of spray residue The matter is not quite so simple Arsenic has been found by reputable investigators, not alone in fruits and vegetables, but in practically every item of the human dietary. The United States Food and Drug Administration, in the course of a nation-wide survey of the arsenic content of practically all classes of food, found in 129 out of 1169 (1 out of every 9) samples analyzed, arsenic trioxide in excess of 01 grain per pound, the so called world tolerance Tish and other marine products are particularly high in natural arsenic. It is not impossible that the intolerance of many persons to fish and shellfish bears a relation to their arsenic content Two of our patients with fairly high amounts of arsenic in the blood, reported urticaria after eating lobster Another, with lichen planus and keratosis of the palms and soles (blood arsenic 16 and urinary arsenic up to 136 mg) complained that his rash was always worse after eating fish

In order to satisfy our curiosity as to the amount of arsenic which a person might take into the system in a day, on an ordinary diet, we made out the accompanying menus, on which have been listed the amounts of arsenic found by various investigators in samples of the food in Of two or more analyses reported on the same food, we have usually, although not always, cited the higher, but we have not cited figures representing exceptional conditions, for example, fruit purposely oversprayed for experimental put poses According to the authors' descriptions, the original samples were either bought on the open market, or were taken, in the case of some fruits and vegetables, from orchards, truck gardens, or interstate shipments of commercial growers, consequently they represent foods which would normally find their way, under present-day conditions to the table of the consumer The fact oi dinary amounts up to and in many instances exceeding these have been found by competent investigators in such a variety of foods in common use, means that the mystery of arsenic findings in patients without any history of arsenical medication ceases to be a mystery The total amount of metallic arsenic for the three sample meals would be more than ten times the amount contrined in a maximum duly dose of Fowler's solution as prescribed by the present writer (allowing five drops three times a day, of a one per cent solution of potassium arsenite)

If it be contended that in any such aibitrary selection and arrangement of foods as the present one, amounts much greater than "average" are represented, and that no person would be likely to hit upon this particular aggregation of arsenical foodstuffs in a day, it can be claimed with equal propriety that he might easily happen upon a still larger total The cabbage on the luncheon menu, for instance, high as it is in arsenic, contains only one fifteenth of the amount of arsenic found by the Baltimore City Health Departmet in one sample of cabbage already on the market The cauliflower, another "high," represents an interstate shipment seized by Federal inspectors for excessive residues of arsenic and lead This would be reassuring if we could be certain that all such lots were seized before reaching the market The strawberries and blueberries reported here were admittedly sprayed shortly before picking, and no rain had fallen in the meantime have no assurance, however, that this

does not hold true of many lots of berries which reach the public markets. will be said that washing and peeling removes most of the poison, but not all fruits and vegetables can be peeled-disregarding the loss of vitamins when they are—and that part of the public obliged to eat in public eating places has nothing to say about the washing of its food. Those who wash their own must reckon further with the fact that many arsenical sprays contain less than one per cent of arsenic in water-soluble form (sometimes not more than one-half of one per cent). Commercial growers are learning to use hydrochloric acid and degumming agents to partially remove these residues before shipping their products. This is impracticable for the small grower and for the ordinary consumer.

If the average citizen wishes to go in wholeheartedly for an arsenical diet, he has made only a good beginning on his regular meals. If he enjoys an occasional glass of wine, he may find arsenic up to two mg. per liter in samples analyzed by Berg and Schmechel, 15 to choose a recent report from numbers available in the literature. Three to twelve mg, per liter were found in the wine responsible for the poisoning of French sailors occurring If one would drink an extra glass or two of milk, .15 to .19 parts per million may be added in this way. 16 Codliver oil contains, according to Sadolin,17 3.9 parts per million arsenic, or up to 5.1 parts per million, according to Holmes and Remington.18 One may easily get .5 mg. metallic arsenic from a single apple,

if one credits the statements of Lynch,19 who performed thousands of painstaking analyses for the United States Department of Agriculture. A single pear containing the amounts found by the Los Angeles County Board of Health in some of their samples, would supply 6.5 mg, metallic arsenic. If the consumer smokes, he probably inhales, in which case the smoking of 2.6 ounces of pipe tobacco would give him as much arsenic as the law permits in one pound of food. This is based on the average findings of Gross and Nelson.20 Individual samples ran considerably higher; cigars and cigarettes averaged slightly lower than pipe tobacco.

We take for granted that our drinking water is free from arsenic, vet arsenic has been demonstrated in the water of many European city systems, and in this country Shelden²¹ has traced a case of multiple neuritis to arsenic in drinking water from the faucet (2.5 mg. arsenic per liter). Ayres²² found the equivalent of 3.33 mg, metallic arsenic per liter in wellwater used by a woman who presented almost every known symptom of arsenical This same writer within the poisoning. past year reports that a questionnaire sent to the Department of Health in every state in the Union brought replies from forty-four states admitting that no routine tests had been made for arsenic in drinking water. In Illinois the aluminum sulphate used for purification of the water contains one to three parts per million arsenic. An inquiry addressed by me to the New York City Bureau of Water Supply brought the information that their

laboratories had never tested the water for arsenic, but that the report from a recent spectrographic analysis had not mentioned the presence of arsenic. The danger of contamination is greatest in mining and smelting areas, but since arsenical sprays are used on the watersheds supplying most city systems, it would seem highly desirable to have periodic examinations made.

By this time the discouraged consumer is likely to inquire whether we do not take in arsenic with the air we breathe. The answer, unfortunately, is "yes," for arsenic occurs as an impurity in coal, and hence in smoke and soot, which account for most of the arsenic reported by various investigators in atmospheric dust. Limitations of space preclude touching upon innumerable substances in which arsenic occurs, either as an essential constituent or as an impurity carried along in some commercial process unfamiliar to the average user.

Comments

Significance of the form and mode of intake of arsenic. It is not the purpose of this paper to arouse exaggerated fears in regard to arsenic. The cases already cited in which arsenic was at first suspected but the real cause of the trouble was found to lie elsewhere, should show the necessity for a healthy skepti-Furthermore, the toxicity of arsenic varies to a considerable extent with its form and mode of intake. The work of the Swedish Commission indicates that surprisingly large amounts of arsenic can be ingested, especially with fish and other marine products, without at least producing immediate ill-effects. The explanation of this probably lies largely in the individual's ability to excrete the arsenic before it can be stored up in the system, and this would depend partly on the functioning of the excretory apparatus and partly on the form in which the arsenic Bang's²³ studies suggest is combined. that organically combined arsenic is eliminated more rapidly and with less danger to the organism than arsenic in inorganic The fact that most of the arsenic contained in spray mixtures is in insoluble form undoubtedly explains why there are not more universal epidemics of acute poisoning from this source. The changes undergone by arsenic once it is taken into the digestive tract are still largely a matter of conjecture.

Also the physical state of the arsenic is an important consideration, and is closely linked to the question of habituation. The ability of arsenic eaters to consume amounts ordinarily fatal (up to 51/2 grains of white arsenic, according to Schäfer) without apparent ill-effects are in all probability due, not to habituation to the drug as has been commonly assumed, but to the eating of the dry powder or crystals in fairly coarse particles. Such an amount, if it dissolved at all rapidly, would probably constitute an oral lethal dose for a man, but its actual toxicity cannot be stated, where the degree of fineness is unknown. Schwartze's experiments on animals showed an enormous difference in toxic effects, depending on whether the arsenic trioxide was administered in soluble form, in powder, in fine or in coarse crystals. The finer the state of sub-division the more toxic the preparation proved; the lethal and emetic doses of the coarsely divided arsenic were often many times the corresponding doses of the finely divided and dissolved forms. Up to ninety-five per cent of the solid arsenic trioxide could be recovered from the feces, while the dissolved arsenic was eliminated through the urine. Schwartze's²⁴ analysis of the literature on the subject disclosed a lack of conclusive evidence that any noteworthy degree of habituation to dissolved arsenic trioxide has ever been attained.

Another angle of the same problem was investigated by Morishima²⁵ who wished to verify the claims of Besredka that he had succeeded in immunizing against lethal doses of arsenic, and that the serum of immunized animals contained an "antiarsenine." Morishima, on the contrary, found that neither a small preliminary dose given twenty-four hours before the lethal dose, nor fractioning the lethal dose in four parts given every three to four hours, nor small doses gradually increased over a period of four months, produced any appreciable immunity.

The effects of arsenic also vary somewhat depending on whether it is ingested, inhaled, or absorbed through the external skin. But by any and all routes, it seems to be capable of producing systemic poi-

soning as well as local symptoms. Many cases of poisoning by inhalation of arseniuretted hydrogen have occurred among chemists and industrial workers. The hemolytic effects of the gas usually predominate over other symptoms, resulting in hematuria or hemoglobinuria, with strangury and in severe cases, complete anuria, also jaundice of an intense coppery hue. In one case communicated to me personally by Dr. Roth, of Los Angeles, a healthy young man who worked for eleven hours spraying with the arsenical mixture "KMG" (Kills Morning Glories) and inhaling the spray as he worked, began to pass bloody urine within a few hours after he stopped work. It was not until several hours after this that he was seized with nausca, profuse vomiting, and watery diarrhea. stools and vomitus were also bloody. Arsenic was demonstrated in the urine. The patient recovered. In some trades where workers inhale dust contaminated with arsenic, nose and throat symptoms are characteristic, often leading to ulceration and perforation of the nasal septum which have been mistaken for syphilis.

What is "normal" arsenic? On this hinges the interpretation of arsenical findings in pathological conditions. One should be cautious in accepting any standard quoted as "normal" without knowing the author's use of the term. It has been used by many in the medicolegal sense to apply to arsenic which may have been taken into the system by any means other than criminal or accidental poisoning. In this sense, arsenic derived from medication would be "normal" arsenic. We restrict the term here to that found in healthy persons without history of arsenical medication or any other known source of intake. This phase of our work is still in progress, but figures are available on a limited number of cases.

In twenty blood samples taken from sixteen healthy children between the ages of two and fourteen years, we found an average of .0529 mg. arsenic per 100 gm. of dry specimen. The individual specimens ranged from .000 to .15 mg. We also took samples of blood from fifty-five young healthy adults recently infected with syphilis but as yet untreated. So far as could be ascertained, these patients had never taken arsenic in any form. Their blood averaged .2598 mg. Six had none or a trace only; sixteen had

less than .1 mg.; twenty-eight had .1 mg. to .9 mg.; and three had more than 1.0 mg. The average for the adult group is five times as great as that of the children's group. This suggests cumulative properties and is in line with the findings of Billeter and Marfurt.20 who reported that in the organs and tissues from seventeen cadavers ranging in age from newborn to seventy years, all without history of arsenical medication, arsenic was found in all, in amounts increasing with age. If we put together our seventy-one normal persons of all ages, we would have an average of .2046 mg. arsenic derived solely from incidental sources.

The average amount of arsenic found in the uring of the group of normal children was .130 mg, per liter (21 specimens from 16 children). Analyses are not yet com-pleted for the urines of normal adults, and were available on only a part of the patients with the various dermatoses already discussed. Ideally one would wish systematic examinations of both blood and urine from each patient, but where this taxes too beavily the laboratory facilities, we believe that the blood arsenic provides a better index of tolerance for the arsenicals than the urinary arsenic alone. A low urinary arsenic may mean poor excretion, rather than a minimal intake, while a high urinary arsenic, in our experience, usually paralleled a low blood figure, and represented some measure of the patient's ability to eliminate the poison, once it has been taken into the

system.

When the figures for "normals" are compared with those found in patients with the various pathologic conditions already examined, it is evident that the "normals" average considerably less even than the patients with the milder dermatoses such as acne and vitiligo, and very much less than those with more serious skin ailments. On the other hand there are individuals in the normal group showing a much higher amount of arsenic in the blood than some patients with pathologic conditions. This factor of individual tolerance must be reckoned with. It occasionally happens that of two persons living under identical conditions, one will show considerable amounts of arsenic in blood or urine and yet be free from symptoms, while the other, with lesser amounts of arsenic will display symptoms of poisoning. One may see from Table II what differences exist among members of one family, on the occasions when analyses were made of the blood of two or more members on the same day.

All this is not so surprising when one

remembers that the effects of arsenical poisoning may be indirect. Most or all of the arsenic may have time to be eliminated, but the pathologic changes wrought in the liver and other organs persist, as alcoholic cirrhosis of the liver or kidney may cause death long after the ingestion of alcohol has ceased. Vogel's27 studies indicate that the liver can take up large amounts of arsenic without giving rise to any clinical signs, until some intercurrent disease suddenly brings on symptoms of poisoning. Something of this sort may account for the cases of dermatitis or "eczema" which appear to be brought on by contact with sundry banal substances hitherto tolerated, when the blood examination reveals a retention of arsenic.

Another factor not always taken into apparently negligible account is the amount of arsenic which suffices to bring on a recurrence of symptoms in a person once poisoned. Among the poisoning cases reported by Althausen and Gunther29 patient recovering after a months' hospitalization for an arsenical neuritis with partial paralysis, suffered a sudden temporary relapse characterized by nausea, abdominal pain, general muscular tenderness and stiffness in the extremities, immediately after eating some cookies sent him from home. Analysis of the remaining cookies showed .0015 mg. arsenic per 100 gm. It is inconceivable that a healthy person should be affected by so small an amount, yet in a person already poisoned it seems to have called forth a reaction of sensitization. One of our patients who had suffered repeated recurrences of poisoning symptoms traced to the eating of sprayed fruit, reported an acute gastrointestinal upset after drinking pineapple juice, although he had previously taken it without ill effects. A sample of the same brand analyzed in our laboratory showed .0047 mg. arsenic in sixteen ounces of the juice.

It is only after observing the problem from these various angles that one grows less inclined to ignore the occurrence of even relatively small amounts of arsenic either in foods or in the body fluids. From a superficial examination of our findings in normal persons, one could of course conclude that amounts up to or even (in a few cases) exceeding 1.0 mg. arsenic may

be present in the blood without causing any damage. The question is: how much arsenic is already being stored up in the body (we have mentioned evidence of its cumulative properties), and how long will this particular individual be able to retain so much arsenic before clinical evidence of poisoning appears? It seems probable that the arsenic taken in from foods, etc., —at least that portion not immediately eliminated—accumulates gradually in internal organs, whence a portion is set free from time to time into the blood stream, a portion only being eliminated. In our patients with dermatoses and a low blood arsenic on admission, it was noticed that sodium-or calcium thiosulphate therapy was almost invariably followed by a temporary rise in both blood and urine arsenic, suggesting mobilization of the metal from internal storage depots, and an attempt to excrete it. The more active the urinary excretion, the more rapidly the blood figure was observed to decline. Of the comparatively few patients whose first blood or urine specimen was reported free from arsenic, every single one showed some arsenic in blood or urine on subsequent occasions, except one patient with acne who lapsed before a second specimen could be taken.

Obviously, there is no such thing as "normal" arsenic in the sense that one uses "normal" for essential constituents of the blood or body tissues. As a foreign element, arsenic is tolerated in varying degrees depending on a concurrence of Chief of these in the light of our present knowledge, appear to be (1) the physical and chemical state of the arsenic ingested, absorbed or inhaled; (2) the ability of the organism to maintain an equilibrium between storage and excretion; and (3) individual differences. either constitutional or acquired, which may render an organism highly susceptible locally at certain times to amounts hitherto tolerated.

Practical Suggestions

Perhaps out of the foregoing one may venture to emphasize a few practical considerations in regard to chronic poisoning by arsenic:

1. Even the most typical symptoms are easily mistaken for other conditions: the gastroenteritis of the acute stage has fre-

quently passed for ptomaine poisoning, the nose and throat symptoms for influenza and syphilis; the pigmentation has been mistaken for Addison's disease, and the cutaneous eruptions for everything from measles to erysipelas. It is not difficult to believe the story that in former times the faithless and designing spouse would dip her husband's shirt in an arsenical solution; the result would be a rash simulating a syphilitic eruption and thus suggesting marital inconstancy on his part. In short, since almost every known type of cutaneous eruption has been observed in connection with arsenical poisoning, and since there is furthermore the possibility that many conditions not generally attributed to arsenic may owe their inception to it, either directly or indirectly, we believe that every eruption or pigmentary disturbance that cannot be definitely identified by supporting evidence as due to other causes, should be open to suspicion as a manifestation of arsenical poisoning. With this attitude, the physician is less likely to make the all too common mistake of prescribing arsenic for a condition which may owe its inception to that very substance.

Concerning opportunities for the intake of arsenic, although it is the part of wisdom to attempt to seek out a definite source, in view of the widespread occurrence of arsenic in foods and other substances in everyday use, one should not dismiss the possibility of arsenical poisoning merely because one fails to establish a history of arsenical medication or of exposure to some other known source. Under our present day living conditions it would be infinitely more difficult to prove that a patient has not been exposed to arsenic. Analyses of foods-especially fresh fruits and vegetables, hair tonics, etc .- may furnish valuable evidence. careful study of the patient's habits and environment will often be necessary in order to establish the chronology of exposure and onset, exacerbation or regression of symptoms.

3. The examination of blood and urine for arsenic is important not only to establish a diagnosis in a particular case, but also to help in building up a more comprehensive body of knowledge concerning the fate of arsenic in the human system, and what, if any, may be considered the limits of "normal' arsenic. While there are comparatively simple qualitative tests for arsenic which can be carried out by the physician himself or by a lay assistant, it is better to send the specimens to a laboratory for a quantitative determination. Many reports in the literature are of doubtful value because of inadequate data as to the quantity of arsenic found, or the method used to determine it.

4. In examining for other causes of the dermatosis or other ailment in question, we always take one or more Wassermann tests to exclude syphilis (only one patient in our entire series showed a frankly positive Wassermann). Patch tests are done with drugs and external irritants, and patients suspected of food idiosyncrasies are examined in the Allergy clinic. Repeated examinations for fungi are done in doubtful cases. When the patient gives a history of employment in any industry or occupation which might expose him to any particular hazard, such as lead poisoning, this angle is always investigated. In a number of our cases the urine was examined for lead as well as arsenic, but in only one case was lead found in any considerable quantity, and in this case the arsenic far exceeded the lead, while typical symptoms of lead poisoning were lacking. This needs to be taken into consideration both in connection with paints, and with fruit sprays, where lead-arsenate is the preparation of choice, and the lead residue may exceed the arsenical.

Treatment with sodium—or calcium thiosulphate, either by injection or by mouth, or both, hastens the excretion of such arsenic as may be stored up in the system, and is the remedy of choice in the present state of our knowledge. regularly observed a rise in blood and urine arsenic immediately after beginning treatment, to be followed shortly by a gradual but steady decline as the treatment was continued. Local applications and light treatments can of course be used to supplement this for certain skin conditions, although we frequently saw marked improvement follow the use of sodiumor calcium thiosulphate alone.

 Finally, we would emphasize our belief that the effects of arsenic as observed in the majority of cases of chronic poisoning are due not to the arsenic derived from any single source, but from the combined effects of arsenic taken in from a multiplicity of sources and in a great variety of forms. Under presentday living conditions it is probably impossible to remove a patient from all contacts with arsenic.

Summary and Conclusions

- 1. A series of 107 patients with a variety of symptoms was investigated from the point of view of possible arsenical poisoning; seventy-one healthy persons were used as controls, and comparative studies of the blood and urine of both groups were made for retention of arsenic.
- 2. The cutaneous manifestations and other associated symptoms were compared with those observed in known cases of arsenical poisoning, and evidence is also presented that some conditions not generally attributed to arsenic may be caused or aggravated by its retention in the system.

- 3. Attempts to trace the sources of this arsenic have been described, and results of numerous investigations of foods, wallpapers and other substances in common use summarized from both published and unpublished data.
- 4. Typical case histories have been given in brief, showing that removal of the source and/or treatment designed to hasten the elimination of arsenic were followed in many instances by clinical improvement or cure, and that this improvement usually paralleled a reduction of arsenic in the blood. Re-exposure to arsenic was followed by recurrence of symptoms and a rise in blood arsenic.
- 5. The question of "normal arsenic" has been discussed, and some practical suggestions are offered for the guidance of the general practitioner and with a view to stimulating further research.

NEBRASKA'S "AIRPLANE DOCTOR"

Dr Frank A Brewster, of Holdrege, Nebraska the "urplane doctor," has flown more than a million miles in looking after the needs of the people he serves in Repub lican Valley in southern Nebraska and northern Kansas He specializes in surgery, operates duly in two hospitals which are almost 150 miles apart as the highways twist and turn, and draws his patients from a territory that covers about 25,000 square miles

He supports two hospitals, three airplanes and an airport All the money that comes in to him goes right out into hospital and airplane equipment. The up-to diteness of his hospitals-one in Holdrege and the other in Oberlin Kansas-is his pride and joy He has no interests outside his profession, not even aviation, strange as it may seem This amizing country doctor, who has developed into a famous flying surgeon, looks upon the plane merely as a means to an end Tast transportation saves hours that mean lives

An amusing story in Dr Brewster's career, as told in The Sportsman Pilot, concerns one of his early pilots, Hodge Smith happened that now and then in an emer gency operation that had to be performed on the spot, Pilot Smith was called to help the doctor He developed, as Dr Brewster puts it, "quite a technique" Not only that, Smith became so interested in surgery that he gave up flying and took up medicine Today, Dr Brewster likes to relate with a deep chuckle, Pilot Smith is Dr J Hodge Smith of Mars, Pennsylvania

The relaxation Dr Brewster finds in the air is necessary to him, for the flying physician is a hard worker Winter and summer, rain or shine, he flies his 230 mile patrol between the hospitals at Oberlin and Holdrege Frequently, when emergency cases pile up thick and fast, he flies the stretch three times a day It is not unusual for him to fly to Oberlin at dawn, operate all morning, return to Holdrege, spend the afternoon in the operating room and fly back to Oberlin to attend another patient. He often goes on flights of mercy to the sick in other towns and out-lying Since most of the country is flat districts and hard, it is usually easy for him to find a landing place near the spot where a marker on a windmill or barn roof tells him he is needed

The American Medical Association has let a contract to remodel and modernize the headquarters buildings at 535 North Dearborn St, Chicago, and add two additional stories and a pent house auditorium

In Germany the buying and selling of medical practices is prohibited, but a certain amount by way of compensation for the delivery of a physician's leasehold and equipment including instruments, may be agreed on, in which transaction the local chairman of the Kassenarztliche Vereinigung must serve as an intermediary

Workers in hazardous occupations, those driving vehicles and elevators, working with moving machinery, and in plants where hazardous substances are used, need periodic a check up of the eyes. This involves more than one ordinary Snellen test. The mere fact that an employee had a pre employment examination does not preclude the necessity of re examining him from time to time

Pasteurization of certified milk results in a product that averages less than one hundred bacteria per cubic centimeter, accord ing to Dr M J Rosenau, president of the American Association of Medical Malk Commissions

The fourth annual George Washington University post-graduate clinic will be held this year on Saturday, February 29, at the University Hospital from 9 00 A M until 4 30 P M All physicians who are interested are cordially invited to attend the meetings

THE ASSOCIATION OF FRACTURES AND PAGET'S DISEASE (OSTEITIS DEFORMANS)

CLARENCE A. TRAVER, M.D., Albany

From the Departments of Surgery and Surgical Pathology of the Albany Hospital and Albany Medical College

In 1877, and again in 1882 and in 1889, Sir James Paget¹ wrote on "A Form of Chronic Inflammation of the Bones" which he called osteitis deformans, using a term which had been employed before that time to cover a variety of conditions. In all he studied twenty-three cases and gave the following classical description of the disease:

The disease begins in middle age or later, is very slow in progress, may continue for many years without influence on the general health, and give no other trouble than those which are due to the changes of shape, size, and direction of the diseased bones. Even when the skull is hugely thickened and all its bones exceedingly altered in structure, the mind remains unaffected. The disease affects most frequently the long bones of the lower extremities and the skull, and is usually symmetrical. The bones enlarge and soften, and those bearing weight yield and become unnaturally curved and misshapen. spine, whether by yielding to the weight of the overgrown skull, or by change in its own structure, may sink and seem to shorten with greatly increased dorsal and lumbar curves; the pelvis may become wide; the necks of the femora may become nearly horizontal; but the limbs, however misshapen, remain strong enough to support the trunk.

Describing his first case Paget wrote:
The shape and habitual posture of the patient were thus made strangely peculiar. His head was advanced and lowered so that the neck was very short, and the chin, when he held his head at ease, was more than an inch lower than the top of the sternum. The short narrow chest suddenly widened into a much shorter and broader abdomen, and the pelvis was wide and low. The arms appeared unnaturally long, and though the shoulders were very high, the hands hung down by the thighs and in front of them. Altogether the attitude in standing looked strangely in contrast with the large and handsome features.

Paget's disease existed in ancient times and in many races as a study of the skulls and bones collected in various archeological museums shows.² The name

"osteitis deformans" was used by Sir James Paget because the bones of his patients showed gross thickening, elongation, and deformity. This applies only to the advanced forms of the disease with involvement of many bones, but localized forms of involvement also occur without gross deformity, and many of these probably go unrecognized. Statistics as to the incidence of Paget's disease vary widely from approximately one in 40,000 among outpatients at the Massachusetts General Hospital³ to one in 3,000 among patients admitted to the Peter Bent Brigham Hospital, as reported by Bird who attributed his high incidence to the fact that eighty per cent of the patients had been examined radiographically. Hurwitz⁸ reported the incidence at the Johns Hopkins Hospital as one in 10,000. At the Albany Hospital the author found twenty-five cases among patients admitted during the last twelve years, an incidence of approximately one in 4,000. There were thirty-six other cases examined radiographically but not admitted making a total of sixty-one cases.

Schmorl⁶ found Paget's disease in three per cent of autopsies in patients past forty years of age (80 in males and 58 in females) and reported the following distribution in the bones of the 138 cases:

Sacrum 7		21
Vertebrae 6	9 Clavicle	
Skull 3	9 Ribs	10
Sternum 3:	2 Humerus	ě
Pelvis	0	

Jaffe² states, "it is not a rare occurrence to find roentgenologic evidences of quite unsuspected Paget's disease in the pelvis, for instance, of a patient who has vague symptoms of pain in the back. Such lesions have been known to show lack of any considerable progression when followed over a period of years." The longest duration of the disease which the author could find recorded was fifty-two years. The date of onset in these cases is necessarily approximate only, depending as it does on the patient's observation and on the severity

of his symptoms. Many writers state that the skull, the fibia, and the fenur are the bones most frequently involved, but this is probably not true in view of the studies made by Schmorl on the 138 cases that came to autopsy. It is now generally conceded that the earliest changes in Paget's disease are to be found in the spine and sacrum. It has been stated that the fibula is rarely if ever involved; however, I found it involved in two cases.

The onset of the disease is usually insidious. There may be vague pains in the back or extremities or local bone deformity such as enlargement of the skull or anterior bowing of one or both tibiae with or without pain. Indeed pain is a very variable symptom in Paget's disease. It is attributed by Elting' to distention or stretching of the periosteum, and he believes that the pains are most marked during the early stages of the disease. The absence of pain in certain instances he attributes to a slow development of the disease with less stretching of the periosteum. The eighth case reported on this continent was reported by him before the Albany County Medical Society in 1900 and published the following year in the Johns Hopkins Hospital Bulletin. With his permission I am including this case in my report. The joints are not directly involved in Paget's disease, but there may be some disability in the joints because of interference with motion due to thickening and deformity of the adjacent bones.9 Hence, these patients are clumsy and likely to fall. Arteriosclerosis is regularly found associated with the disease, but this may be a coincidence Heredity is a doubtful factor. Deafness is common due to pressure on the auditory nerve if the skull is involved, and it may be an early symptom.

The etiology of Paget's disease is still unknown, but it is hoped that the recent studies of the parathyroid glands and their relationship to the metabolism of calcium and phosphorus will throw some light on the subject. Parathyroids have been removed from patients with Paget's disease and improvement is said to occur, 10 but hyperparathyroidism has not been proven to be present. The levels of calcium and phosphorus in the blood are normal in Paget's disease, and there is no parathyroid hyperplasia. 11 For the present, it would seem wise to limit parathyroid sur-

gery to patients in whom hyperparathyroidism can be proven by adequate metabolic studies. In this regard it should be said that one must not put too much reliance on a single determination of blood calcium and phosphorus. It is now generally recognized that patients with osteitis fibrosa cystica, or von Recklinghausen's disease, are suffering from hyperparathyroidism and can be benefited by parathyroidectomy.

In the pathology of Paget's disease¹³ the characteristic change is enlargement of

Fig 1. Picture from Paget's original article published in 1877.

one or more bones with replacement of normal bone by bone of a spongy structure. The bone marrow later becomes fibrous and new bone is formed in the marrow spaces. There is first softening and then overgrowth of bone. In the long bones there is an increase in width and some increase in length as well. During the early stages the bones are soft and cut easily with a knife; it is at this stage that the deformities occur. Later there is a thick deposit of subperiosteal bone, and the surface of the bone becomes rough and irregular. The porous nature of the bone can best be demonstrated by pouring water into the thick skull cap, when it will be found to escape as through a sieve.14 In the radiographs are seen thickening of the cortex with enlargement and bowing of the long bones and a rearrangement of the trabeculae into strands or bundles running longitudinally. The new cortical bone may show multiple longitudinal cyst-like areas. The medulla also shows mottled areas of rarefaction which extend into the epiphysis. This involvement of the epiphysis is important in the differentiation from lues which rarely affects the epiphysis in the same manner. The skull changes are often most characteristic. We can visualize these best if we imagine that

the curled kinky hair of the negro has undergone calcification. 16

There are conflicting statements in the literature as to the incidence of fractures in Paget's disease and as to the effect of the disease on the healing of the fractures in involved bones and in uninvolved bones. Jaffe² believes fractures are not so rare as the literature seems to indicate and states:

The tibia and femur are the bones most easily fractured in Paget's disease, and frac-

Fig. 2. Interior view of calvarium from a patient with Paget's disease showing deep excavation of bone by the cerebral blood vessels. Note great thickness of bone and dark marrow. The bone can be easily cut with a knife.

tures occur often after slight trauma and may sometimes appear spontaneously. As the callus goes through the various stages of calcification and ossification, it becomes involved in the pathological process, and the new bone also shows roentgen evidence of Paret's disease

He concludes that the fracture may heal completely though somewhat more slowly than normal. A rather high proportion of these patients develop osteosarcoma, particularly at the site of old fractures, according to Maes,17 for the regenerated bone seems to have a special predisposition to sarcomatous change. While a number of writers (DaCosta, Carman and Garrick,18 Hurwitz,5 Love,10 and Lewin20) consider fractures rare or infrequent in Paget's disease, others (LeWald.21 Auffret,22 Maes,17 Locke,23 and Jaffe2) believe fractures are common or at least not unusual. Incomplete fissures are common and with slight trauma may become complete fractures, and multiple fractures in the same individual, in the same or different bones, are not uncommon. There is also a great difference of opinion as to the rate of healing in fractures associated with Paget's disease. A few have reported early healing, i. e. more rapid than in normal bone.24 Non-union seems to be rare. Among the sixty-one cases studied at Albany Hospital the author found seventeen instances of fracture, and in fifteen of these the fracture was in a bone involved with Paget's disease Of course, it is dangerous to make deductions from so small a series, but the following conclu-

sions seem to be warranted:

(1) Normal union occurred in one-third of the cases, and delayed union occurred in an equal number of cases; (2) Early union occurred in one case, a fractured femur; (3) Non-union occurred in one case which developed a sarcoma at the site of the fracture (ischium), and death followed three years after the injury from metastases to the lungs; (4) No record could be found as to rate of healing in three fractures

Of these fifteen patients, five had multiple fractures. In three instances the humerus was fractured twice, and one of these patients also fractured both scapulae. In one instance the radius was fractured four times. One patient had a fracture of the femur and later fractured the tibia and fibula. So the total number of fractures in the fifteen patients was twenty-five. All the fractures united except in the one case which developed a sarcoma at the site

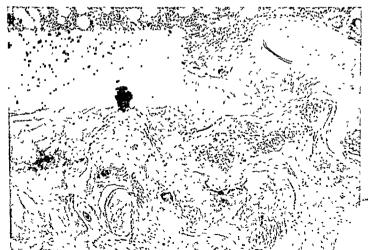

Fig. 3 At upper border vers active marrow. Very thick trabeculae of bone which is por calcium and resembles osteoid tissue. Marrow spaces show marked fibrosis and dilated very

of fracture and died of metastases. Two patients with Paget's disease had fractures in bones not involved in the pathological process; both showed delayed union.

I am indebted to Dr. Howard and to other members of the staff of the Albany Hospital for the privilege of reporting these cases. 99 Washington Ave.

RESULTS IN 15 CASES IN WHICH THE FRACTURED BONE WAS INVOLVED WITH PAGET'S DISEASE

Identification	Age	Ser	Site of fracture	Union	Extent of involvement with P. D.

THE PATHOLOGY OF FATAL BIRTH INJURIES

WILLIAM E. STUDDITORD, M.D., New York City

During the year ending June 30, 1934, 1.751 women were delivered of a total of 1,771 babies on the Bellevue Hospital Obstetrical Service. Of these infants 1,596 were discharged living and in good condition, while 175 died from various causes and slightly under 80 per cent were autopsied. The gross fetal mortality was therefore 9.88 per cent. Fiftyseven of these cases were non-viable, while thirty were either macerated at birth, fetal death having taken place before labor or early in the first stage, or presented anomalies considered incompatible with life. Correcting the mortality for these cases we find a percentage of 4.96. When we further consider that forty of the remaining eighty-eight cases were premature, we find that the mortality of term infants, stillborn but not macerated or dying within the period of hospitalization of the mother, amounted to 2.7 per cent.

Birth injury played a great part in the remaining group of 48 for one-third (16) of these infants coming to autopsy were found to have sustained injuries to the central nervous system and its protective covering, or to the abdominal viscera. In addition, in 22 per cent of the non-viable and premature infants evidence of injury was found. The purpose of this treatise is to discuss the nature of these injuries, the possible method of their production, and the clinical picture which they produce. The chief injuries found may be divided into three main groups: (1) the intracranial, (2) spinal, and (3) intraabdominal.

Intracranial Injuries

Anatomy. A clear understanding of the protective structures of the brain together with the dural sinuses and the venous drainage of the brain, is of the greatest importance in interpreting the intracranial lesions. The skull of the new born infant is soft and yielding, and during the course of normal labor must undergo considerable change of size and shape. Serious damage results when this change, known as moulding, is carried too far or occurs too abruptly. The dural senta serve in the adult to divide the cranial cavity into compartments and to carry the large sinuses. In the fetus they serve in addition as internal supports to the cranium and prevent sudden or excessive changes in size and shape of the cranial cavity.

The dural septa are two in number and are formed by reduplications or folds of the lining membrane of the cranium. The falx cerebri is a thin sickle shaped septa extending from the crista galli of the ethmoid bone in front to the internal occipital protuberance posteriorly. Its upper border is attached to the cranial vault in the mid-line, just beneath the sagittal suture. Its lower border is free, with a concavity. Within its folds course two large sinuses, the superior and inferior longitudinal sinuses. The tentorium cerebelli is the large tent-like septum that roofs in the posterior cranial fossa and separates the cerebrum from the cerebel-In general form it is crescentic, the longer convex border lying behind and attached to the posterior and lateral margins of the posterior cranial fossa, and the shorter concave anterior border curving backward and upward from the anterior clinoid processes. The upper surface of the tentorium is held taut by its attachment to the falx cerebri along its entire median plane. The free tentorial border forms the incisura tentorii, an arched opening. The highest point of this opening lies just behind the corpus callosum. The fibres of the tentorium pass from one side to the other and decussate with those of the falx so that two distinct layers are found.

These septa are not equally strong

From the Department of Obstetrics and Gynecology, New York University College of Medicine and the Obstetrical and Gynecological Service of the Third (New York University)
Surgical Division, Bellevue Hospital, New York City, Read at the Annual
Meeting of the Medical Society of the State of New York, Albany, May 14, 1935

throughout, but it is found that the strongest fibres come into play in resisting cranial stress when the fetal head is fully flexed—the normal position during labor. Between the folds of the tentorium lie several large sinuses. The straight sinus runs directly backward between the layers of the tentorium along the line of junction with the falx to the occipital protuberance. Here it is joined by the superior sagittal sinus and splits to form the lateral sinuses. At its anterior end it is joined by the inferior sagittal sinus and the great cerebral vein. The latter vein drains both right and left cerebral veins, receives tributaries from the cerebellum, and passes free and unsupported from the corpus callosum to its point of juncture with the straight sinus. right and left cerebral veins receive blood from the veins draining the base of the brain and lying beneath the floor of the lateral ventricles. The latter vessels are frequently ruptured in the premature. The great cerebral vein is singularly open to tension when the junction of the falx and tentorium changes position. This obviously must occur during moulding as will be shown later. The intracranial hemorrhage occurring in term infants, is due to laceration of the vein or of its tributaries, not to ruptures of the dural septa which tear as a rule through an avascular

Forces coming into play during labor and their effects. During even the most normal labor the soft parts exert enough resistance to result in some change in shape of the fetal cranium. changes are marked in the case of actual disproportion when strong uterine contractions are present. They are resisted by the intracranial septa. Gradual slow changes in shape take place as a rule without harm. When force is applied excessively or abruptly the fibres in the dura snap and marked changes in the shape of the cranial cavity take place. Antero-posterior compression results in raising of the vault of the cranium with consequent elevation of the junction of falx and tentorium, and tension on the great cerebral vein and its tributaries. Excessive and sudden antero-posterior pressure results in a rupture of the tentorium at a rather uniform point, about one centimeter lateral to its junction with the falx. The subsequent increased tension on the great cerebral vein results in rupture of the vein itself or of its tributaries. Subdural hemorrhage follows and is usually small in amount rarely producing bulging of the fontanelles. Since the force producing these lesions never ceases following this damage, excessive changes in the shape and size of the cranial cavity ensue with resultant cerebral There is little or no gross evidence of this cerebral injury but microscopically small perivascular rhages may be found. Lateral compression results in an elongation of the cranial cavity and increased tension in the falx. Excessive or abrupt lateral compression results in large tears in the substance of the falx. Cerebral injury due to loss of cranial support may follow this.

The above description covers adequately the intracranial injuries found in term infants. These injuries occur most commonly in vertex presentations when forceps are applied unskillfully, or when the fetal head is drawn through the least suitable pelvic diameters; in breech deliveries when disproportion exists or when the proper mechanism of labor is ignored; and, least commonly, in precipitate labor with abnormally strong maternal forces. Often they are inevitable, due to a pardonable mistake in judging the relation of fetal size to maternal pelvis, or due to the necessity for interference because of the failure of maternal forces. Eighty per cent of the intracranial injuries found in term infants belonged to this type.

There exists another set of forces during labor which does not affect the term infant other than to produce a marked hemorrhagic edema of the fetal scalp in cases of dry labor. It is possible that temporary changes due to this force take place in the intracranial cavity. In the premature infant these forces may produce fatal effects, but as a rule they do not come into play until the membranes have ruptured. During a uterine contraction the portion of the fetal head exposed in the undilated cervix or rigid vaginal introitus becomes a point of low pressure in relation to the rest of the fetus. The abundant scalp veins and lymphatics in this area tend to become engorged and distended. The dural sinuses and small arachnoid vessels also become distended because of

these forces The vessels in premature feti are poorly developed with very weak walls and cannot withstand distention In addition to edema of the scalp, the premature sustains edema and diffuse hemorrhage of the small arachnoid veins, and sometimes because of the reflection of pressure along the intracranial sinuses, rupture of the thin-walled veins lying beneath the floor of the lateral ventricles with production of large subventricular or intraventricular hematomata. This type of lesion is never seen in the term infant but is characteristic of the premature These injuries are caused by the natural forces of labor and are most often seen in spontaneous deliveries. They may occur during cervical dilatrition or while the premature head is being forced through a rigid introitus. The shortening of premature labor by low forceps and episio tomy will save many fetal lives Twenty per cent (21 cases) of the premature or non viable babies showed this variety of lesion Few showed dural lacerations

Clinical thenomena Infants who sustain intracranial injuries and who survive delivery, present the picture described as "asphyxia pallida" They are very pale with a faint weak heartbeat, the respira tions are absent or are slow, shallow and irregular, and the muscle tone is practically gone Their condition is one of shock and is analogous to concussion in the adult Many require artificial methods of respiration and may show temporary improvement following their use During the next few days the infant is apathetic and refuses to nurse Often they steadily become worse with increasing cyanosis, and die Should they survive forty eight to seventy two hours, the outlook is hope ful, and several have been followed who show no apparent permanent effects From the nature of the lesion described active treatment is contraindicated. Complete rest and quiet would seem to be an important factor in recovery. Evidence of a true hemorrhagic diathesis is rarely present

In the premature infant, the clinical picture is less typical since in most instances the injury is less severe. It would seem likely that these injuries play a part in the apathy and feeding difficulties of many premature infants.

Spinal Injuries

Anatomy The fetal spine is not a sturdy structure found in the adult ligaments are poorly developed and the spinal column is made up of segments of cartilage and connective tissue with rela-Under traction it is tively little bone capable of elongating considerably tained in the spinal caml and attached to to the walls by nerve roots and vessels, is the spinal cord which is relatively in-Elongation of the spinal column must result in injury to the vessels and nerve roots which pass from the cord to the spine, injury to the cord itself, and finally in rupture of the spinal column

Forces coming into play during labor and their effects Injury to the spinal column and cord occur almost always under two circumstances (1) most commonly during breech extraction, and (2) occasionally in vertex presentations in large babies when, following the delivery of the head, the shoulders become impacted in the brim of the pelvis. The mechanism is essentially the same. When a breech extraction is attempted under proper conditions, the fetal body responds to slight traction. During the latter part of the procedure the shoulders or head may become impacted in the brim of the Excessive traction, now against a fixed point, results in elongation of the spinal column, rupture of spinal vessels and finally in rupture of the spinal cord and spinal column Torsion and angulation of the spinal column combined with traction, increases the possibility of these mjuries They are often associated with intracranial injury Because the head is the most frequent point of impaction, injury is most frequently found in the lower cervical vertebra, the point where angulation of the spine under symphysis and torsion of the spine occurs The spinal column injury is a separation of the epiphysis from diaphysis of one of the vertebra The spinal cord injury is marked first by hemorrhage about the cord and in more severe instances by partial or complete rupture. The cord is involved for several segments above and below the point of rupture so that in the cervical cases the medulla is involved

The prevention of accidents such as this

lies in reduction of breech presentations by antepartum external version, and by careful gentle technic in breech extraction, with proper attention to the mechanism of labor. Less force should be used in dealing with vertex presentations complicated by impacted shoulders. Four such cases were found at autopsy, two occurring in breech deliveries and two in vertex deliveries with impacted shoulders.

Clinical picture. Those infants suffering marked injury to the cervical cord never survive birth, Certain of the brachial palsies are due to cervical spinal cord lesions. Cord injuries below this point show the picture of a trasverse myelitis and often survive for many years.

Abdominal Injuries

The two organs involved are liver and adrenal. The liver injury consists of the rupture of a small vein beneath the capsule of the liver. Unless death occurs due to an associated injury, a gradually increasing hematoma develops, and as a rule after thirty-six to forty-eight hours, rupture takes place and profuse intra-abdominal hemorrhage occurs.

This injury may occur in a spontaneous labor, especially in a labor that is prolonged, dry, and with powerful uterine contractions. Badly applied abdominal pressure often used to assist the second stage may be a factor. Frequently these are seen following breech delivery and are caused by the operator grasping the upper abdomen of the fetus in performing extraction. Violent efforts at resuscitation may be a cause.

The adrenal injuries result from rupture of a thin-walled vessel in the medulla with the production of a growing hematoma which attains large size and destroys the gland. These hematomata are almost always bilateral and are most frequently found in babies dying after breech extraction. They are caused by the operator grasping the upper abdomen of the fetus tightly during the delivery.

The clinical picture in these cases is very similar. Providing there is no associated intracranial or spinal injury these infants appear quite normal during the first twenty-four to thirty-six hours. Then they become apathetic, refuse to nurse, and die within twelve to twenty-four hours. Five such injuries were found among the term babies and two in prematures. The most hopeful method of dealing with this type of case again seems to lie along the lines of prevention.

Conclusion

One must conclude that the greatest means of improving the fetal and neonatal death rate in this group of cases lies along the lines of prevention. This knowledge can only be acquired by autopsy of all still births and infants dying in the neonatal period, not by the general pathologist, but by a pathologist well acquainted with the conditions under which these injuries occur. This necessitates a closer relationship between clinical obstetrics and pathology than is found in most institutions.

Of the three main types of cases, the term infants with mild cerebral injury offer the best prognosis as far as complete recovery is concerned. The best form of treatment in these cases is absolute rest and quiet until definite improvement begins to take place.

768 PARK AVENUE

"HERE'S HOW" BACTERIA SPREAD

The increasing prevalence of trench mouth in the United States was attributed to insufficient washing of the rims of cocktail, high ball, and beer glasses in a paper presented by Dr. Don Chalmers Lyons, of Jackson, Mich., before the Society of American Bacteriologists at its thirty-seventh annual meeting at the Hotel Pennsylvania in New York City. Other spirochaetes, some of them carrying diseases more dangerous than trench mouth, he reported, were found in surprisingly large numbers among the bacteria on the rims of glasses racked upon

the bars of taverns and saloons selected for his experiments.

Although alcohol is itself an antiseptic, he said, it seemed to have had little effect on the trench mouth germs.

The large percentages of Vincent's stomatitis, or trench mouth bacteria, he suggested, showed that "proper methods are not being taken in beverage dispensing establishments to prevent the spread of this disease. It suggests the necessity of better control of methods of glassware cleaning in such establishments."

RADIUM THERAPY

Douglas Quick, M.B., F.A.C.S., New York City

At the present time there still exists a certain degree of confusion as to the relative position of radium in irradiation therapy. Throughout the profession in general, this confusion is due largely to the rapid and popular advances of x-ray therapy during the past few years. Within irradiation circles, it is increased by the placing of too great a burden on our present day x-ray therapy—a burden predicated on hope rather than fact and experience.

It is the purpose of this brief communication to couplastice the steadily increasing value of radium in the treatment of cancer, and to attempt a clarification of its relative position in the more limited

sohere of irradiation therapy.

The treatment of the neoplastic diseases today is dependent almost entirely on surgery and irradiation therapy. The profession is rapidly coming to appreciate the advantages of combined methods of treatment; the one-time impression of competition between surgery and the physical agents is being steadily replaced by a realization of their complementary relationship. The same relation exists between radium and z-ray, but, unfortunately, it is not as clearly recognized. Perhaps it was recognized at one time, but is for the moment transiently forgotten because of the rapid progress of x-ray therapy.

It is not the purpose to discuss here the possible advantages, pro or com, of these two physical agents for external distance application. We are concerned for the moment with the strictly practical side of every-day clinical work. In the amounts now available and with the distribution as it is, radium is not practical for telecurie-theraple, except in an extremely limited fashion. X-rays represent the practical source of energy for external distance irradiation over large areas. Radium, on the other hand, is adaptable to application within body cavities and particularly for placement in some form directly within the tissues. It has an important, yet

limited, value for surface application over small areas only. With this general adaptability of the two agents, I am sure are all, for practical purposes, agreed.

During the earlier years of radium therapy, very definite and encouraging results were obtained in the treatment of some forms of malignant disease. These results, however, were obtained by empiric methods and often at the expense of much suffering on the part of the patient, incident largely to gross tissue destruction. Results obtained under such circumstances are prone to be forgotten, or rather submerged, by the unhappy and lasting imprecsion of physical suffering left in the mind of the casual observer.

As time went on and experience accumulated, many of the undesirable features of radium therapy were eliminated. The maximum fisue-tolerance decage with radium has been fairly well-established. The influence of complicating mixed infection on this tolerance is well-recognized. The response of various histological types is all the while better understood. It is now just ten years since it has been possible to employ radon interstitially in filtered rather than unfiltered seeds. This, together with the other factors mentioned, has eliminated in a large measure the problem of gross destruction of tissue by radium irradiation.

Added to certain of the early and unfavorable impressions of radium therapy in the mind of the profession at large, has been the unfortunate new-paper publicity attendant upon certain commercial uses of radium element. This unfavorable publicity, while having no relation whatevever with the therapeutic application of radium element or radon, has created a measure of skepticism with a section of the public. During the past few years radium element or radon in any desired form has been readily available for use by any member of the profession choosing to employ it. Some of the commercial companies providing this service have not been as conscientions as others

in the selection of those to whom they have furnished it.

Criticism, however, on this point should not be limited to the commercial companies. Many institutions and some individuals owning small amounts of radium have elected, for economic reasons, to farm out their radium, when not being used personally, to those having little experience in the use of what may easily be a dangerous agent. The economic conditions of the past five years tend only to encourage such practice. The general practitioner, and those of the profession having only a casual interest in irradiation therapy, are not apt to analyze the individual case very deeply; they are not apt to investigate and to distinguish between many of the unfortunate results of such practice and the real progress which has been made during the past few years through the use of radium in experienced hands. Many in the profession have neither the time nor the opportunity to investigate the real progress. There are, therefore, many physicians in an extremely favorable frame of mind to accept what they may regard as a substitute or competitive agent. This at once places an unfair burden on x-ray therapy.

The earlier experience with x-radiation was discouraging. Later, with higher voltages, better results were obtained. With added experience these were improved. The background existing between radium and x-rays has been quite different. The initial encouraging results with radium were obtained, very broadly speaking, through overdosage; x-rays it has been just the opposite. Initial encouragement was through the use of what we now regard as very small doses indeed. The only overdosage with x-rays came with the introduction of the 200 K.V. equipment, and here the overdosage was on the basis of individual exposure rather than total dosage. This was soon recognized and various methods of fractionating the dose promptly instituted to avoid the undue constitutional effects of the heavy individual exposures. Today we have excellent equipmentthanks to the engineers—and a very high degree of accuracy in the measurement and control of x-ray dosage, through the aid and cooperation of our physicists.

Much of the experience gained through

the earlier empiric radium work has been applicable to the building up of our present excellent high-voltage x-ray therapy. Many of those most deeply concerned with x-ray therapy have been for years slowly and steadily working out the details of fractionating and spacing x-ray dosage in order that the patient may derive the maximum of benefit with minimum of local and constitutional adverse effect. It remained for Coutard to give popular expression to this phase of the work. He did not by any means set forth a new method of x-ray therapy. He did. however, give concrete expression to a very definite principle in 200 K.V. x-ray therapy—namely, daily or semi-daily exposures, consistent with the patients' individual constitutional tolerance, and carried over a substantial period of time —frequently several weeks, much heavier filtration than is ordinarly employed, and a very slow rate of delivering the individual dose. This work was done entirely, almost entirely, with epidermoid carcinomas involving the hypopharynx.

Coutard's work was widely published. Within the radiation group we are most deeply indebted to him for his foresight as well as his courage in visualizing and carrying through to a successful conclusion such an excellent piece of original and advanced work. His work has touched such a note of popular response throughout the profession in general, as well as with a large section of our public, that its true value is in serious danger of being discounted; too much has come to be expected of it. Many physicians in general practice, or engaged in the other specialties, have today the impression that everything of value in irradiation therapy is embodied in the so-called Coutard method of x-ray therapy. As a matter of fact, relatively few x-ray therapists are equipped to carry out the Coutard principle of treatment. Many of those who are adequately equipped regard it as economically impractical for their particular work. It is time-consuming because it makes use of but a small percentage of the actual output of radiant energy from the high-voltage tube. As a result, all sorts of modifications are being indulged in, vet the impression very carefully retained, and all too often advertised, that the Coutard treatment is being adhered to.

It is obvious that this is unfair not only to the practitioner who cannot be expected to be familiar with all detrils of such work, but more particularly to the patient who is staking his chances on what he is led to believe is the best procurable in treatment Granting, however, that the Coutard principle of therapy is well carried out, and granting also that this principle is applicable in reasonable meas ure to many types of malignant disease and in various locations throughout the body, we must not lose sight of certain other important facts. We must remember that we are still dealing with a form of radiant energy adaptable only to external use In its application we are limited ultimately by the skin tolerance of the patient Any attempt to gain just-a little more of advantage over the malignant growth by increasing the x ray intensity beyond this ultimate skin tolerance results in irreparable damage

We should pruse at this point to recall that we have a source of radiant energy which will permit increasing the local intensity within the tumor bearing area to the desired level without overdoing the x ray therapy I refer, of course, to the use of radium element in needles, or to radon seeds, for interstitial implantation throughout the tumor-bearing area, after a reasonable amount of x ray therapy has been given. It is in the failure to recog mize this very point that so many un necessary irradiation failures come about The x ray therapist at the present time is prone to forget the values of radium for increasing the local intensity of the destred dose The same criticism obtains with the radium therapist in attempting to accomplish more than is practically feasible with his agent alone combination of the two that fulure is fre quently turned to success

In present day cancer therapy, there is no place for the isolationst. Familiarity with all methods is essential to the best interests of the patient. This holds equally true for the surgeon who assumes responsibility for the care of the cancer case as for the radiation therapist, whether the primary interest of the latter be in a rays or in radium. The cancer therapist must take advantage of all possible ands it all times, if the curability of cancer is to be improved upon. After all, there

are few of the major types of cancer in which at some place along the course of treatment two or all of these methods or agents are not found to be advantageous in the carrying on of the treatment to best advantage. In some instances it may be a matter of selection as for instance with that large group of growths involving the skin surface, or, more frequently, however, it is a matter of utilizing to best advantage the proper method or agent, in the proper place and in proper sequence

Take for instance that vast group of epidermoid carcinomas involving upper mucous membrane tract We now know that they present a wide range of histological variation-consequently they have a wide range of relative radio sensi Coutard, and many others as well, have shown that many of the primary growths in the hypopharyny and larynx are curable through x-ray therapy alone without operative surgery and without the use of radium. One must remember, however, that many of these growths have metastasized to cervical nodes these metastatic nodes show a marked response to the x ray beam which cures the primary growth, relatively few of them are completely eradicated by that The x ray therapist is apt to be misled by this favorable initial response and disillusioned only several months later when the remnant of the metastatic node gradually takes on renewed growth is then much more resistant to any form of therapy We know that these socalled radio sensitive growths are very highly malignant in that they are prone to early and wide spread dissemination For this reason metastatic nodes are but rarely curable by the older method of radical surgical neck dissection ever, we take advantage of that favorable period when the node is reduced and qui escent, following the x ray therapy, expose it surgically and implant it with radium element or radon seeds, the chance for cure is very much greater many of the primary growths in the mouth and throat, particularly those be longing to the intermediate grades from a radio-sensitivity standpoint, surface healing and consequently relief from immediate symptoms should not be accepted with too much enthusiasm. Here again implantation with radium tremendously enhances the probability of permanent cure. The preliminary x-ray therapy is a great aid to the subsequent radium therapy, in that it reduces the growth, aids in clearing up the surface ulceration, and consequently the surface infection, so that a radium dose of lesser intensity may be introduced with much less risk of infection. The radium dose adds tremendous assurance to the permanence of the result initiated through the x-ray therapy. In other words, the one physical agent is strictly complementary to the other.

For several years now radium has been regarded as the agent of choice in the treatment of carcinoma of the cervix uteri. We now know that with the improvements in our x-ray therapy, the results are infinitely better if pelvic irradiation with x-ray precedes the direct and local application of radium. More recently it has been found that intensive irradiation therapy rivals, if in fact it does not replace, operative surgery in dealing with many cases of carcinoma of the fundus uteri. Just because symptoms are controlled by x-irradiation and because the growth is not amenable to direct inspection, does not mean of necessity that the growth is completely controlled. It is a simple matter to introduce heavily filtered radium into the fundus of the uterus, if carcinoma of the fundus is to be irradiated rather than removed by hysterectomy. Such treatment is most certainly not complete unless radium is employed by intrauterine application in conjunction with the external x-ray therapy.

In carcinoma of the breast, x-ray therapy is obviously the method of choice for pre- and postoperative irradiation in the operable group of cases. However, any experienced surgeon knows how frequently unexpected findings turn up in the axilla at the time of operation. No surgeon who assumes responsibility for the care of a case of breast cancer should proceed with the operation without having

available for immediate use a suitable supply of radium in case some unexpected finding of metastatic involvement precludes the finishing of his dissection, as he had hoped and anticipated would be possible.

There are so many instances in which radium is of value for use at operation that the space here available would not permit an attempted enumeration. In addition to the value of interstitial radium irradiation at the time of operation for extirpation of growth, there are in turn many instances where surgical exposure of the tumor is essential to proper and accurate radium or radon placement.

The point I wish to convey is that the general management of cancer in all of its types and phases is, in general, a surgical problem; that we have extremely valuable aids in both radium and x-ray therapy, and that a familiarity with both of these physical agents is essential to meeting squarely our responsibilities to the cancer sufferer. Furthermore, I wish to point out the fact that there is very little competition between surgery and irradiation therapy. Best results are obtained by a combination of all three measures rather than by stubborn adherence to one or the other alone. Especially, however, I wish to point out that in the more limited sphere of irradiation therapy, one must not be misled by the very encouraging and at times spectacular results from x-ray therapy alone. It enhances the benefits to be obtained from radium, but it does not replace them. The two agents should be used in very close coöperation, rather than in the spirit of attempting to cover the irradiation phase completely by either one or the other agent alone. Radium and x-rays are neither antagonistic nor competitive in adaptability or effect. They are strictly complementary. A closer combination of the two agents invariably reacts to the benefit of both and decidedly to the advantage of the patient. 350 PARK AVENUE

"QUACK DOCTORS—DEATH DEALERS"

In sentencing a former barber named Kenneth Barron to jail for practicing medicine without a license, Judge Erwin J. Hasten of Chicago said: "Quack doctors are death dealers and a menace to the reputable medical profession. In reality, they prevent

ignorant, gullible persons from getting the services of competent physicians. Instead of healers they become killers indirectly." Barron operated the "Madison Western Clinic" which advertised medical service at cut-rate prices. One death occurred at the clinic.

CHRONIC ENCEPHALITIS

Care and Treatment of Patients Found in State and Municipal Hospitals

ORMAN C. PERKINS, M.A., M.D., F.A.C.P., Brooklyn

Professor of Neurology, Long Island College of Medicine

The importance of the study and care of patients suffering with chronic encephalitis and especially those who show abnormal mental states, is still neglected by both municipal and State authorities. A census shows a constant increase of such cases in the chronic wards of our municipal hospitals, and the same condition exists in the State hospitals for the insane. In considering this problem one is confronted with certain questions which should be analyzed carefully before it can be said that these people are receiving the attention they deserve.

(1) Do the patients who are victims of chronic encephalitis found in the State institutions for the insane really belong in such an institution?

(2) Should the psychiatric reactions observed in such patients be sufficient to classify the patient as a definite case of psychosis?

(3) If the patient is not psychotic, should one not consider the environment in which he is placed?

(4) In such institutions to which all types of psychosis are committed (and as we know the institutions are already overcrowded), do these patients receive the proper treatment?

(5) Is it possible to carry on methods of investigation which may produce the best results in an institution of this type?

(6) If there are psychotic manifestations present, are they not associated with and in most cases undoubtedly the result of organic brain disease?

(7) Since it is possible to check the progress of this disease and to relieve the most troublesome symptoms to some extent, does the State not owe this attempt to each individual case?

(8) Should patients suffering chronic encephalitis lethargica be kept in the chronic wards of Municipal hospitals?

considering the postencephalitis mental syndromes we must divide them into two groups. Those that are found in children and those that are prevalent in adults. It is the general opinion that behavior disorders are more frequent in younger patients and that bradyphrenia is more frequent in adults. In a consideration of the problems stated above more time will be devoted to the older patients, as they represent a group of people, in the majority of cases, who have had a well-developed brain, have been able to earn a livelihood, enjoyed the pleasures of life, and appreciated the circumstances of their environment.

Steck1 in his study of this problem found that 369 victims of encephalitis had been in Swiss asylums for mental disease and that 257 of these cases showed evidence of Parkinsonism. Although the author has no figures for the institutions throughout this country it is certain that the proportion is even greater than in

Switzerland.

In these cases associated with Parkinsonism there is noted in every case a mental slowing, but this does not depend necessarily on the severity of the Parkinsonism. Bromberg2 in a recent article pointed out that careful psychometric examination of the adult cases have failed to demonstrate the presence of any real intelligence defect. Von Economo has placed emphasis upon this same observation in his latest publication on encephalitis lethargica and its sequelae.

Special attention is called to the fact that this holds for adults rather than children, as one would expect a defect in the latter due to arrested development of the brain. Although these patients show narrowed fields of interest and sometimes an indifference in regard to personal affairs, they still maintain an affective contact with their families as well as unimpaired memory, judgment, and orientation. The appearance of the patient, especially in advanced Parkinsonism, as well as his reactions and responses might lead one to assume that the patient is an advanced case of dementia.

But if one persists in analyzing this type, one is soon impressed with the mental integrity and clearness; and one finds the type can offer an explanation on a basis of "weakness" or the "impossibility of making certain movements," often interpreting the asthenia that is so marked as some form of paralysis which has arisen out of the great effort it requires to move the limbs. Sight must not be lost of the fact that this patient is a lay person and the peculiar change that has come over his entire body as well as his activities is far more of a puzzle to him than it is to the professionally trained mind that still has much to learn about the condition.

The changes in the emotional state of the patient must likewise be carefully studied. The so-called emotional duliness that is observed in a large percentage of cases may be more apparent than real. Since the person of this category is restricted by the fixation of facial muscles and by poverty of all volitional movements in his attempts to demonstrate emotions, one has to get behind the mask for the true answer. Many neurologists have had the experience of watching the marked improvement of such patients, placed upon treatment. These patients show a change in their emotional sphere as well as in their activities. Many realize their unhappy condition and feel correspondingly dejected. Should one consider this reaction an abnormal state of mind, or should this expression of their thoughts be expected? At any rate, there is very little in such a condition to be happy over.

Although euphoria is observed in a small number of cases, the incidence appears to be most frequently in younger people. It has been the author's experience that when it is present in the adult, the patient is travelling under false colors. He insists that he is improving and that he feels fine, yet he is only utilizing the psychology of the Coué treatment, hoping, merely, that his desires will be fulfilled.

The cases that have been described in which obsessions and compulsions occurred, though not very numerous in the lts, are most often associated with agyric crisis, respiratory disturbances, various types of tics. Anxiety states often associated with all types of the re and they are presumably most in the earlier stages of proin instances where the pathold to a small portion of the

brain. There is an example of this in a case in the Kings County Hospital at the present time, of an adult with segmental dystonia who has an anxiety state so developed that he is continually watching for any change in his condition or new developments.

Many authors in describing the schizophrenic-like states that have developed following encephalitis lethargica admit that only the accessory symptoms of schizophrenia are observable. It has been noted that such important symptoms of schizophrenia as true negativism, poverty and dissociation of thought, and antism are absent. The majority of these patients generally remain in contact with their environment.

Schilder has pointed out that these patients show a certain self-criticism with regard to their delusions and may be easily influenced by persuasion, also that in contrast to schizophrenia an actual inner splitting of personality does not occur.

Steck believes that the association of schizophrenia with encephalitis may be largely a matter of coincidence. Paranoid and hallucinatory states do occur and Bromberg calls attention to thirteen instances of paranoia and only one of hallucination in 135 cases. It has been noted that these conditions are transitory in many cases.

It is not uncommon to find patients complaining of disturbances of temperature, vasomotor symptoms, paresthesias, dizziness, and palpitation. The obscure pains as well as various compulsions and phobias may be explained on the basis of peculiar bodily sensations. In fact we see same psychic disturbances patients suffering from genuine vasomotor diseases as well as in cardiac conditions. In this disease we recognize the frequency with which vegetative centers have been affected by pathology. Consequently in such cases the neurasthenic state may well be the result of misinterpretation on the part of the patient with his insight and anxiety to explain or discover the cause for such symptoms. The insight that the patients exhibit is well illustrated by their apologetic attitude for their uncontrolled motor activities such as tumors, tics, oculogyric crisis, or attacks of hyperpnea with forced expiration.

It has been my experience that maliciousness, pugnaciousness, stubbornness, lying, disobedience, and irresponsibility are observed in the younger group of cases This group represents an entirely different problem because of the arrested development of the mental faculties Many of these patients are considered behavior problems and because of this classification one is encouraged to believe that one's therapeutic attack should be along psychological lines. The author contends that this form of therapy must not be neglected in the adult cases, as it represents one of the most important forms of treatment

In the careful investigation of the patients whom are found both in state institutions for the insane and the municipal hospitals, one is impressed with the most common reasons for their admission The family has been told that this disease is a chronic progressive disease with no hope for a cure The patient becomes a burden at home The relatives lose interest in attempting to please the patient, or to make him happy They look upon the entire situation as a mere matter of time and are embarrassed when their friends visit the home and note the patient's condition This attitude generally means neglect of the patient, who becomes despondent on this account That is why he shows such a marked degree of depression or despondency on admission to the institution. He realizes, moreover, that he has been in the way, and that, because he is a burden, he has been making his relatives unhappy

Granted that most patients who suffer from chronic encephalitis shows certain abnormal mental symptoms, is one justified only in the exceptional cases in making a diagnosis of psychosis? Observation teaches that many of these patients should not be classified as psychotics and consequently should not be kept in institutions for the insane. These people have a marked degree of insight and realize the type of institution they are in Thus it is difficult to attempt the type of psychological treatment for the best results The mere fact alone that they are in the society of other patients who show psychotic manifestations, that they themselves can recognize, gives them anxiety Invariably they ask the physician "Will this disease affect my mind?" and "Do you think that I will go crazy?" That is why it is unfortunate for the patient to find himself detained in an institution as an insane person associating with insane people Even with his own sanity quite intact, what chance have those in charge to make progress with psychological therapy?

Frequently these patients are admitted to the acute neurological wards of municipal hospitals, only to be transferred after a short time to the chronic wards, either because beds are scarce or because the case is incurable. The patient, realizing that he has been labeled an incurable and placed back on the shelf for future reference rather than for daily attention, comes face to face with the hopelessness of such diseases as multiple sclerosis, myopathies, paralyses, and the like The environment. what with bed ridden patients in the overcrowded wards, which place him in a poor state of mind, impair circumstances favorable to psychological therapy

The literature is full of descriptions of various syndromes resulting from this disease. The results of laboratory investigation and pathological examinations are all exceedingly important and still to be desired The field for investigation that offers most to the patient is the treatment Food and shelter is necessary, but more is deserved than these. The effects of certain forms of medicinal treatmenthyoscine hydrobromide, stramonium, duboisine sulphate, and atropine-are well known 'An arrest of the progress of this disease for long periods of time and the relief of the most annoying symp toms to some extent have been noted The greatest satisfaction is obtained when individual attention is applied to the patient, not only from the medicinal point of view, but from every angle, including regulating daily routine, outlining diet, planning activities both as to play and useful endeavors When this patient realizes that he is a patient and not simply an inmate or boarder, the first milestone towards success in changing his outlook on life will have been passed

The author would call to the attention of the state authorities the weak links in present methods of handling this problem He would plead with them to sense fully their responsibility to these their fellow men who have been so unfortunate as to be afflicted with this dread disease. He would recommend, moreover, that at least one institution be erected to handle these cases alone, this institution to be carefully planned and the site well-chosen. It should, first of all, be located in the country and have sufficient grounds to meet the requirements for exercise. The State spends millions on parks for the healthy; why can it not afford a park for the sick?—for the chronic encephalitis sufferers who need sunshine and exercise? They are still capable of thrilling at competition and games—inside or out. Many of them are card and checker enthusiasts. and when such games are arranged in tournaments for them the spirit is increased. Though the great number of these persons would be well satisfied to sit and listen to the radio, this should not be allowed and can, with proper supervision, be avoided.

The general physical condition should be thoroughly investigated and watched. All foci of infection should be removed. The care of the teeth in the patient is often neglected, especially since there is an excess of saliva, with the teeth decaying early. Since the metabolic rate is low in many cases, infections produce a greater drain upon the system than it would in the case of a normal individual. The weight should be recorded regularly and the diet regulated. It is even necessary to watch the fluid intake of many of these patients since even the effort of eating and drinking is too great for some. The responsibility of the care of the bowels should be placed upon those in charge, and not upon the patient.

The patient appreciates interest taken in his behalf and there is no easier way to obtain his cooperation. He becomes more eager to do things for himself and takes pride in attempting systematic routine. He has less time to think about his affliction and disability. The outlook upon life changes, and a smiling countenance takes the place of anxiety, despondency, and thoughts of suicide. Human, after all, he is still concerned with the pleasures of the world. The State, it seems, ought not to deny him the facilities for diversion and amusement, particularly when even those who have committed crimes against the State can have this privilege.

An institution of the proper sort would also provide opportunity for investigation and research, particularly if its medical staff is selected on a basis of interest in encephalitis as well as on ability. This institution should be the central plant for all State cases, including those found in the municipal hospitals. Since the mental role is so important, these cases would seem to be as misplaced in the municipal hospital as are the psychotic. Procrastination in attending to the necessities and welfare of the sick is neglect and no longer excusable. The nature of the disease is well-known, and so is its scope. witness the large number of victims in our institutions. For that reason it would seem that the problem deserves attention immediately. It will not do to pigeonhole it for some future date.

DR. SPANKSTER'S SUCCESSOR

Children as young as three years old are being treated for mental disease at the Babies' Hospital in the Medical Center at Broadway and 167th St., New York City, according to Dr. William S. Langford, director of the clinic there. No baby is considered too young for consideration.

About 10 per cent of the child patients at the Vanderbilt Clinic were found to have physical ailments arising from some mental

disturbance, and these are now referred to Dr. Langford.

Refusal to eat, Dr. Langford pointed out, may be due to emotional rather than physical causes. Thumb-sucking, vomiting, crying, nail-biting, continual fighting, fear of darkness or animals, are some of the bugaboos with which the clinic deals.

The result of the treatment Dr. Langford said, is considered successful.

INFECTION OF SOFT TISSUE BY GAS PRODUCING ORGANISMS

Early Recognition by Roentgenograms

Report of Five Cases

L R LINGEMAN, BS, MD, Rochester

Director of the Department of Raentgenology Rochester General Hospital, Rochester N Y

The possibilities of early recognition of infections of soft tissue due to gas producing organisms by means of roentgenograms are fairly well known among roentgenologists and rather widely utilized, while on the other hand, surgeons are not generally aware of the advantages of this procedure and seldom use it. It was widely used during the World War The delay in making the diagnosis from clinical findings unnecessarily jeopardizes the life of the patient and increases the mortality Because this method has such definite advantages over any other method known at present and because of the seriousness of such infections, it seems worth while to briefly detail the procedure and report five cases illustrating its possibilities

It is a well-recognized fact that many bacteria produce gas when inoculated into soft tissue under certain conditions. The group that is of the greatest importance from the clinical standpoint is the Clostridium of which about one hundred members have been classified, most of which are saprophytes Seventeen are pathogenic for some form of animal life and only seven of these are truly patho genic for man 1 Of these seven, we are concerned with only two Clostridium Welchii (B perfringens, B Welchii, the gas bacillus) and Vibrione Septique (B of malignant edema, Clostridium edema tous maligni, Clostridium septicum) The remaining members either are so infrequently found or produce so little gas that they are of little importance in this connection

That gas in soft tissue may be recog mized in a film is well known. This may be due to air introduced by trauma of some sort. If so, the gas shadows will be seen in the immediate vicinity of the wound and subsequent films will show a progressive decrease in the amount, ex-

cept in a case due to pleural injuries and some sucking wounds near a joint

On the other hand, gas produced by in fection tends to increase in amount and spread away from the wound. The roent-genological and clinical picture will vary with the virulence of the organism, the number introduced, the length of time, the amount of soft tissue injury and contamination, and the resistance of the host. If the infection is virulent and involves muscle, the inuscle fibers may be separated, while on the other hand the collections of gas may be more circumscribed.

In 1931 Rhinehart² reviewed the hterature and reported thirty cases. Eleven cases were diagnosed by films on an average of nine and one-half hours after injury and with a mortality of eighteen per cent against the clinical recognition in fifty and one half hours and a mortality of fifty per cent in nineteen cases.

Rhinehart showed that one cc of air injected into soft tissue could be demonstrated in a film and he was able to recognize one case within two and one quarter hours after injury. I was able to demonstrate gas infection in four hours. Experimentally, Strauss' showed that gas could be demonstrated within four hours after inoculation.

Routine films will usually suffice, although care must be exercised that the gas shadows are not "blackened out" of the film On the other hand, sufficient time must have elapsed for the production of sufficient gas to be visible

Case I MK, No 45969, white, female age ten, admitted August 23, 1930, at 5 20 PM on account of a compound fracture of the left radius

The wound was debrided and the fracture reduced at 7 00 PM on the day of admission On the afternoon of August 25 approximately forty eight hours later, the fingers became blue and crepitation was

Fig. 1. Approximately forty-four hours after injury. (Case I). A well-developed case clinically and roentgenologically.

noted in the soft tissue of the forearm A clinical diagnosis of gas gangrene was made and a roentgenogram examination requested This examination showed an extensive infection extending above the elbow (Fig. 1).

The forearm was immediately opened widely and repeated injections of B. Welchii antitoxin were given There was a spread of the infection to the axilla, neck, and anterior thorax, She showed definite improvement by August 29. However, the circulation of the forearm had been destroyed and amputation was necessary. Cultures were reported positive for B. Welchii on August 29. She was discharged on Oct 15.

Case II. R.U., No 51007, white, female, age sixty-eight, admitted December 5, 1929, because of gangrene of the fourth and fifth toes, right foot, of three weeks duration She had been a diabetic for fifteen years

The area of gangrene continued to spread

and on December 12 a roentgenographic examination was made of her foot to determine if ostcomyelitis was present. This film showed gas in the soft tissue of the forefoot and the question of an infection with one of the virulent gas-forming organisms was raised However, the absence of many of the features of a well-developed case lead to little consideration of this

She had a mid-thigh amputation two days later. On Dec. 15, three days after the report of the roentgenogram examination. crepitation was noted in the stump and autopsy revealed an extensive B. Welchii senticemia.

57885, white, Case III. M.A.R. No female, age seventy-one. was admitted 9, 1930, because of beginning gangrene of the right fifth toe. She had been a known diabetic for six to ten years

The gangrene continued to spread and a roentgenogram examination to determine the question of ostcomyclitis was made on March 13, which resulted in a diagnosis of probable gas gangrene. A second examination was requested. This was made twentyfour hours later and still showed gas present of approximately the same amount (Fig. 2 and 3).

A culture made from the gangrenous area on March 13 was negative for gas forming organisms On March 14 a surgical consultant noted the report of possible gas gangrene and admitted the possibility, advising amputation A mid-thigh amputation was done immediately.

Fig. 2 Note osteomyclitis of fifth toe with evidence of gas. (Case III)

Fig 3 Twenty-four hours after Fig 2 (Case III) Note that gas shadows have not decreased

The patient developed a gangrenous area over the sacrum which had become crepitant by March 20. This area was excised on this date, free gas escaping from the wound. On this same date the laboratory reported

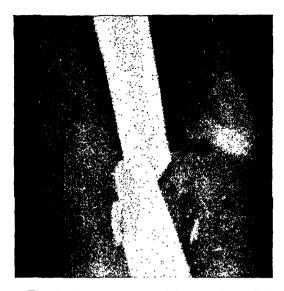

Fig. 4. Five days after injury. (Case IV.) Note shadows of gas in the region of fracture.

a positive culture for B. Welchii from the foot. She developed another gangrenous area over the right buttock with crepitant borders. She died March 29.

Case IV. A.W., No. 87714, colored, female, age five, was admitted on July 29, 1930, because of a compound fracture of left femur which had occurred very shortly before admission.

The roentgenogram examination made immediately after admission showed a fracture through the middle third of the femur. There was no evidence of gas in the soft tissue. The wound was debrided and the fracture reduced.

On August 3 she had a temperature of 103° F, and some pain in the region of the wound. Roentgenogram examination that day showed about a half dozen rounded areas of gas in the soft tissue in the region of the fracture and a diagnosis of gas bacillus infection was made. Her temperature was still elevated the following day. The pain had increased and there was a thick black foul smelling exudate from the wound. A culture was made from the wound. The wound was re-opened and drained. On August 5 the culture was reported as positive for B. Welchii. Her con-

Fig. 5. Four hours after injury (Case V). Gunshot wound. Gas can be seen in the tissues.

dition improved and she was discharged as

well on Oct. 3 (Fig. 4).

Case V. I.R. No. 94932, white, female, age nine, admitted April 9, 1933, at 7:00 P.M. on account of a gun-shot wound of the right thigh which had occurred three hours previously.

A roentgenogram examination made four hours after injury showed a communited fracture of the femur and several areas of gas in the region of the bullet track. A second examination made fifteen hours later showed an increase in the amount of gas, some of which was at a considerable dis-

tance from the wound (Fig. 5).

By 2:30 P.M. of April 10, her temperature had gone up rapidly and her pulse was fast. The wound was swollen, but there was no crepitation. The thigh was opened and drained that afternoon and gas bacillus antitoxin given. She ran a high temperature and was irrational at times until April 12 when she began to improve. At least a part of her condition during this time was due to a serum reaction. One culture was negative She was discharged June 10 as well.

Summary

Five cases of infection due to Clostridium Welchii are reported. One case was recognized clinically and readily confirmed by a roentgenographic examination. Four of the five cases were confirmed by bacteriological examinations; two in four days, one in eight days, and one in two days after roentgenographic examination. Clinically, they were recognized in one case before roentgenographic examination and confirmed in three, seven, and two days respectively.

Conclusions

 Clostridium Welchii and Vibrione Septique are the usual organisms found in virulent cases of gas producing bacilli.

2. These infections carry a high mortality, making their early recognition

imperative.

 These infections can be recognized by roentgenographic examination in many cases before they are suspected clinically.

APPOINTMENTS BY UNITED STATES PUBLIC HEALTH SERVICE

The United States Public Health Service will consider applications to fill a number of vacancies which exist at the present time and also vacancies which will occur about July first next, for second year medical internes. Any young physicians, not over thirty years of age, who have graduated from a Class "A" medical college and who have completed, or will shortly complete, one year's interneship in an approved hospital are eligible to apply.

The Public Health Service desires to

The Public Health Service desires to secure applications only from candidates who are interested in the Service as a career and who desire to request permission to appear before a board of commissioned officers for examination for appointment as Assistant Surgeons in the regular commissioned corps, on or about the time they will complete a year's service as internes in the Public Health Service.

Appointments effective on and after July I, 1936, to vacancies at Marine Hospitals and the U. S. Narcotic Farm at Lexington, Kentucky, will carry a gross compensation of \$1800 per annum, from which a deduction of \$690 per annum will be made if quarters, subsistence, and laundry are furnished. Appointments to vacancies at

Federal Penal and Correctional Institutions will carry a gross compensation of \$1620 per annum, from which a deduction of approximately \$240 per annum will be made by the Department of Justice if quarters, subsistence, and laundry are furnished. Internes are required to occupy Government quarters whenever same are available. Such quarters cannot be shared by any of the interne's dependents.

Those interested in making application should address an inquiry to the Surgeon General, U. S. Public Health Service, Washington, D. C., stating the date they will be available for duty and more complete information and the necessary blanks upon which to make application will be furnished.

If mankind were to make full use of its present knowledge of personal and public health, the expectancy of life could be increased from its present span of 60 years to 75 years, with a corresponding increase in personal happiness and efficiency, Dr. Dean Franklin Smiley, director of the Cornell University health service, told the Public Health Nursing Association of Rochester at a recent meeting.

FIVE THOUSAND GASTROINTESTINAL X-RAY EXAMINATIONS

A Review and Summary of the Conclusions

E. C. KOENIG, M.D., Buffalo

This review was undertaken for the purpose of checking our work with a desire to improve the methods and diagnostic results.

The cases represented in this group were taken from the files in numerical order over a period of ten years ending 1933.

The patients examined are, namely: (1) Hospitalized—referred to us by Hospital staff. (2) Ambulatory—from pri-

vate practice.

The Medical literature is already filled with articles upon the accuracy and scope of Roentgenology as it pertains to the gastrointestinal tract with comparative results of other diagnostic methods, and surgical or postmortem checking of the x-ray findings. Therefore, I will not attempt to enlarge upon the helpfulness of the x-ray method.

A discussion and summary of this review will be made under the following headings: (1) The average age of the patients. (2) Number of each sex. (3) Pathology demonstrated in each division of the gastrointestinal tract. (4) Period of life and sex in which principle lesions occurred. (5) Report on small groups where surgery or postmortem findings can be checked against x-ray findings. (6) Critical discussion of x-ray reports rendered. (7) Lantern-slide demonstration of typical lesions found. (8) Conclusions drawn from this review with suggestions for better cooperation of patient and referring doctors.

Under the above headings were found:

The average age for the group 43.87 yrs. Females 2,697, males 2,303, total 5,000.

Pathology reported as occurring in the following divisions of the gastrointestinal tract with their frequency.

Esophagus	43
Stomach	777
Stomach	///
Duodenum	652
Small gut obstruction	94
Colon	551
Gall-bladder	1 824
Appendix	1,560
Gastroenterostomies	49

Diaphragmatic					ς.
tract) Eventration of	the diap	hragm			3
Pneumoperitone	um		• • • •	• • •	4

There were 848 cases where no pathology was reported so the number used in estimating percentages is 4,152, arrived at by deducting the negative cases from 5,000.

Malignancy was found in 404 cases, which

gives 9.7 per cent of the entire group.

Combining the duodenal ulcer group with gastric lesions there were 1,429 or 34.4 per cent of the entire group having gastric or duodenal lesions or 70.7 per cent ulcer or nonmalignant lesions and 29.2 per cent growth.

The colon lesions were 551 in number: 75.8 per cent nonmalignant; 24.1 per cent malignant. Colitis 295 or 53.5 per cent of colon group, diverticulosis 123 or 22.3 per cent of colon group, growth (CA) 133 or 24.1 per cent of colon group.

The gall-bladder was reported pathological 1,824 times or 43.8 per cent of group with 302 cases showing gallstones.

Pathological appendix, 1,560 or 37.3 per

cent of group reported.

To recapitulate the numerical frequency of the above lesions in percentage of the entire group:

Pathological gall-bladder	43.8% 37.3%
Combined gastric and duodenal ulcers	
with growth of stomach	34.4%
Colon lesions	13.2%

Our opportunity for obtaining surgical and postmortem checks on findings is limited in this group. Most of the cases never reached surgery and cases that were posted were not large in number. Therefore, we are offering the postmortem and operative findings as a check on this group. Sixty-eight cases of gastric malignancy were operated and posted. X-ray findings in these cases were ninety-four per cent correct.

X-ray findings of colon lesions were found to be correct in ninety-three per cent of cases as checked by surgery and postmortem in forty-five cases.

X-ray findings in gall-bladder cases were found to be correct in 80.9 per cent of cases by use of dye, and 59.4 per cent correct in direct method without dye.

Malignancy occurred in life cycle as follows:

Age	Esophagus	Stomach	Color
Under 30		3	0
30-40	. 0	11	4
40-50	14	30	24
50-60		80	54
60-70		66	32 19
Over 70	. 0	38	19
Total	43	228	133

Malignancy occurred in the sexes as follows, females 145, males 259, total 404.

Gastric ulcers occurred in the life cycles as follows: under thirty, 58; thirty-forty, 67; forty-fifty, 228; fifty and over, 196; total, 549. In the sexes as follows: females 227, males 322, total 549.

Duodenal ulcers occurred 652 times as follows: under thirty, 63; thirty-forty, 85; forty-fifty, 264; fifty and over, 240; total, 652. In the sexes as follows: females 209,

males 443, total 652.

Criticism of Reports Submitted in this Series: (1) The x-ray reports in many instances were too long, not always giving clean-cut information, and while all the facts were given, they were not always clearly defined. (2) The reports giving positive information were usually short and clear. (3) Where lesions were not definitely shown, the reports were likewise uncertain, probably so from the fact that an attempt to explain why the lesions as demonstrated were borderline or possible of more than one interpretation. (4) Reading so many reports, one soon was made conscious of the fact that those under forty years of age did not have pronounced lesions. (5) A clear, definite, well-arranged and short report with a conclusion I feel will be the one of my choice from now on.

Lantern Slide Demonstration of Typical Lesions Found: (1) Calcified fibroid found on flat film of abdomen in routine examina-(2) Murphy-button passing down colon. (3) Air under diaphragm following perforation of gastric ulcer. (4) Gastro-colonic fistula. (5) Gallstone slides, gallbladder dye, deformed gall-bladder. (6) Malignancy of esophagus in the lower third. (7) Small gut distended by gas shown by flat films of abdomen in acutely ill cases representing obstruction of the gut without much inconvenience to the patient. (8) Diaphragmatic hernia showing stomach and colon in part well-up in the thoracic cavity. (9) Hour-glass stomach. Residue in hourglass pocket, same stomach after operation, ulcer having been removed, stomach again returning to hour-glass effect. (10) Carcinoma of the duodenum proven by surgery,

not so reported by x-ray before operation. (11) Diverticulosis of the colon. (12) Colitis, severe grades. (13) Colon (CA). (14) Rectum (CA). (15) Megla colon, ten years of age. (16) Stomach and part of colon in thoracic cavity causing no apparent inconvenience to the patient at the age of seventy-two. At the age of seventy-nine she returned for another examination because physician thought the malposition might account for some of her symptoms as per the newspapers, the upside down stomach is the popular one to have or not to have.

Conclusions drawn from this review can be discussed briefly under the following headings: the patient, the doctor, and the

roentgenologist.

- 1. The patient does not always know what to expect from such an examination especially as to the time required. 2. Has the patient just finished with a prolonged duodenal drainage at the end of a long fasting period? 3. Is the patient excited, in the state of fearful anticipation of what the examination is about to reveal? 4. Has the patient an erroneous idea of the scope of an x-ray examination? 5. Some patients are under the impression that the x-ray will show all conditions without the possibility of error.
- 1. Is the doctor seeking help for a proper diagnosis of his case or is the x-ray a mere routine for the verification of a well-established diagnosis made from other laboratory or clinical procedures? 2. Is the doctor in attendance impatient and seeking a report on the x-ray examination before the films have been fully processed? 3. Is the doctor one who tells the patient how many films are necessary for the examination and just how important the fluoroscopic examination is as compared to the films? 4. I feel that often times doctors have hurryitis when it comes to x-ray examinations. 5. This is a place I believe where it might be appropriate to use the old adaze "Haste Makes Waste."
- 1. Has the roentgenologist been trained as such? 2. Is he capable? 3. Is he cooperative? 4. The best results should be obtained from an experienced, painstaking roentgenologist. 5. The roentgenologist should be willing to see his shortcomings and fully cooperate with the patient and attending doctor to fully realize the best results obtainable from roentgenology. 6. The roentgenologist should consider himself a consultant in a given case and so conduct himself. 7. The roentgenologist must be trained, painstaking, patient, experienced, and fully cooperative.

In conclusion, the review of all these cases has been a long and arduous task but I feel that it has been well worth while if for only one thing, that it will help me to do better work in the future and not repeat the errors taken up in this review,

BUFFALO GENERAL HOSPITAL

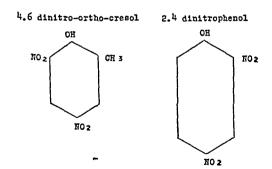

DINITRO-ORTHO-CRESOL

A Metabolic Stimulator and Its Toxic Side-Actions

MILTON PLOTZ, M.D., Brooklyn
Assistant Visiting Physician, Kings County Hospital

For more than a year, medical literature has been flooded with articles about the stimulation of metabolism by chemical substances other than thyroid extract, notably dinitrophenol and its sodium salt. The sale of these drugs has apparently reached enormous proportions because the laity and an inadequately informed section of the medical profession have utilized these substances with results as yet not fully determined. Their toxicology has not been fully worked out and it is possible that there are remote toxic effects beyond the immediate ones so far described. Since it seems altogether likely that other substances more or less closely chemically allied to those now in use will be tried, it appears highly desirable that reports about these unfamiliar drugs be published as soon as possible so that further research, carefully controlled, may be stimulated and so that the profession at large may be quickly acquainted with the drug's toxic properties.

Such a drug is 4.6 dinitro-ortho-cresol first described in this connection by Dodds and Pope in 1933.¹ Its formula is given below with that of dinitrophenol for comparison.

Four successive patients with obesity were given 4.6 dinitro-ortho-cresol in an effort to assess its value in stimulating metabolism. Each was a young vigorous adult in otherwise good physical condition; and the dosage employed to start was .75 milligrams per kilogram of body

weight. Dodds and Robertson² recommended .5 to 1.0 mg. as a safe dose which would increase the basal metabolism thirty to fifty per cent.

Case I. Married female, age thirty-six. Past history was irrelevant. She had been obese since childhood and her mother and two sisters were markedly overweight. Her weight was ninety kg. (28 kg. in excess of normal). Basal metabolism, -3, pulse 70, blood pressure 125/72. She was put on .75 mg. of 4.6 dinitro-ortho-cresol (Eastman Kodak) per kg. of body weight, administered in gelatin capsules since the drug is effective when given orally. She was instructed to follow a low fat, low calory, high protein diet but failed to follow instructions, and reported that her diet during the next two months was essentially that of the five years previous. For the following eight weeks there was no change in pulse or blood pressure and at the end of that period the patient weighed 90.3 kg. She reported no side-actions of any sort except slight headache and lassitude.

During the ninth week the dose was increased to 1.0 mg. per kg. of body weight. She then complained of a sense of great heat and marked palpitations interfering with sleep. The evening temperature was then usually 100.2° F. and at the end of ten days the patient had lost one kilogram. On the eighth day she reported that her sclerae were green. She was instructed to reduce the dose by half and the color disappeared, only to reappear when the dose was again increased. The sclerae were found to be greenish but there was no evidence of true jaundice. No bile was present in the urine and the icteric index was normal. Dodds and Robertson² reported a similar phenomenon in their report, also apparently not due to bile pigments. On the third day following, the patient, without consulting the physician, increased the dose to 1.5 mg. per kg. of body weight and immediately noticed a maculopapular, urticarial eruption, slightly reddish in color, involving both deltoid regions, the upper anterior chest, and both upper axillae. At this time the weight reached eighty-nine kilograms, a loss of 1.0 kg. while under treatment for eleven weeks. The drug was discontinued immediately on the appearance of the rash and no effort was made to continue with it on account of the apparent toxicity. Pulse and blood pressure were never raised throughout treatment

Case II Male, single, thirty years of age, weight eighty two kg (12 kg in excess of normal) Basal metabolism was +6, pulse 62, blood pressure 130/84. The same initial dose as in the above case was given 75 mg per kg of body weight He complained it once of great heat, fatigue, and fullness of the head His temperature was 101° I each night and he was extremely uncomfortable on hot days. At the end of two weeks, basal metabolism was 15 and weight 819 kg. The diet throughout the entire course of treatment consisted of 1800 calories per day including 100 grams of protein Dosage was then decreased to 5 mg and continued for four weeks, at the end of which time the basal metabolism was +12 and the weight was eighty one kg During the last week the temperature rose to 1004° F each afternoon and the patient noticed that there was a transient greenish pigmentation of the eves He felt so uncomfortable that treat ment was discontinued at the end of six weeks

Case III Male, single, thirty-four, weight ninety one kilograms (21 kilograms in excess of normal), basal metabolism -4, pulse 70, blood pressure 110/65 The usual mittal dose was ordered On the afternoon of the second day, the temperature was 1008° F He felt hot, tired, and slightly dizzy On the third day there was a distinct interior tint to the sclerae but the icteric index was normal and there were no bile pigments in the urine The drug was discontinued for two weeks and then resumed with a dosage of 35 mg per kg of body weight On the fifth day theierster the basal metabolism was zero and on the seventh day a greenish tinge to the sclerae was again visible. The patient complained bitterly of perspiration and great fatigue during this time and of the com ments of his neighbors on his "jaundiced appearance" The drug was then discontinued

Case IV is still under treatment having been started at the same time as case III and receiving the same initial dosage. The patient has lost about 6 kg per week for the past six weeks with no untoward symptoms except a sense of fatigue.

The author might include himself as a fifth case having taken for experimental purposes 10 mg per kg of body weight each day for four weeks while on a diet of 2200 calories. There was no unfavorable reaction except a duly rise in temperature to between 1008° and 101° Γ a sense of great heat fullness of the head, and excessive perspiration. There was no loss in weight

Comment

It is apparent from a study of the first three cases that the margin of safety between the therapeutic dose of this compound and the toxic dose is very shin indeed. As a matter of fact, in these cases it was impossible to raise the general metabolism sufficiently to cause a reduction in the body weight without producing side actions serious enough to render further treatment madvisable.

The most striking of these side effects was the pigmentation of the sclerae, to which attention has already been called by Dodds and Robertson. This was apparently no relationship to jaundice, as bile pigments were not discovered in either the blood or the urine. The effect of the drug on the liver, if any, was not determined in this series of cases.

The toxic symptoms therefore may be summed up as follows (1) greenish pigmentation of the sclerae, (2) subjective sensations of heat, (3) fatigue, (4) palpitations and dizziness, (5) hyperpyrexia, (6) excessive perspiration, (7) urticarial eruption. It is noteworthy that neither the pulse nor the blood pressure were reliable guides to treatment.

A fourth case is reported in which satisfactory results were obtained so that it is possible that a larger series of cases may show a much smaller percentage of toxic reactions. Before such cases, carefully controlled, are reported, it would seem wise for most doctors to treat obesity by other methods which have given more satisfactory results.

The dangers of self-medication, particularly because of the publicity recently given to this group of drugs, are tremen dous Case I illustrates how difficult it is to exercise control over even those cases which are under medical supervision. The present educational campaign against obesity should be continued but the public must be warned against self-medication without physical examination Even then, reduction should be accomplished only by moderate exercise and avoiding excessive eating unless carried out under the supervision of a physician Self-sacrifice is at the beginning difficult for most patients especially those who have acquired over a period of many years the habit of overalimentation but it is a small price to pay

and a safe insurance against the dangers of new and comparatively untried drugs.

We should not fail to note that a death due to over-dosage from this drug (marketed as Dekrysil) has already been found in England and reported in the foreign correspondence of the Journal of the American Medical Association.3 Gordon and Wallfield have recently reported a case with toxic reaction to this drug.4

Summary

- 1. Five cases treated with 4.6 dinitroortho-cresol are reported with satisfactory weight reduction in only one case. Toxic reactions were produced in three cases.
 - 2. This compound should be used only

with the greatest caution until further reports are available.

3. Diet and exercise have proved so successful in the treatment of obesity that the use of drugs should for the time being be discouraged. 555 OCEAN AVENUE

THE MYSTERY OF COUNTRY PRACTICE

How to get started in a country practice is a puzzle that formed the subject of an intriguing talk by Dr. Arthur V. Wortman of Curtis, Nebraska, a few weeks ago before the Nebraska State Medical Association. He remarked that the first hurdle is to get patients to submit themselves as subjects. Just what attribute will accomplish that end is a mystery. Why many men of manifestly mediocre ability have offices full of waiting patients, while others eminently better educated and qualified are waiting for business is not explained in any textbooks. One commentator has classified the elements of success as 90 per cent personality, 5 per cent ability, and 5 per cent accident; others give accident a little higher rating.

Advertising is a big element in the building of a country surgical practice. Cure the most prominent citizen of the community of a hopeless case of proliferative arthritis and your bread is buttered for you; open a thorax and closes a stab wound into the heart and patients will beat a path to your waiting room-of course they will forget to pay you, but they will come nevertheless. Operate on an "upside-down stomach" successfully, and get several columns of favorable press notices, and your reputation is made more than merely a local one.

Wherever the country doctor goes he is critically observed, he is the subject of much conversation, the object of many remarks. If he is successful, nearly half of the remarks are complimentary, or at least not derogatory. If he is careless in dress or conduct, he will still have some friends and patients who respect him, if he is foppish or sporty he will have fewer of them. He must follow a conservative course. His city brother can be more independent. People look upon him like we all look upon Cimex lectularius, or the common bedbug. bedbug looks much like any other bug, but it is the way he makes his living that irritates us.

To a select few of his patients the country doctor is a Jenner, a Koch, a Semmeleis, a Lister. To most of them he is just "Doc." To another minority he is a Judas, a Catiline, a Capone, a Dillinger. The city doctor does not enjoy this intimacy.

There's a moral for every physician in the following experience described recently by a Columbus physician and printed in the Ohio State Medical Journal.

Tony, employee of a steel mill, had made no less than a dozen calls at Dr. A's office for treatment for boils.

On the day Dr. A pronounced Tony well and able to return to work, the following dialogue took place:

"What I own you, Doc?" asked Tony, extracting a roll of bills from his pocket.
"Well—Tony—let's see—well—Oh about

-well let's make it \$10", replied Dr. A, hesitatingly.

"Oh, Tony, let's see-Oh-well-let's make it \$10", mocked Tony, tossing a bill on the desk, and continuing:

"Doc, why not \$20; \$30; \$40; \$50; \$100, lika that?

"Why don'ta you talka like you mean it? "Why you no maka me feel you sava my

"Why you no maka me feel you oughta get bigga money for good work?

"Doc, don'ta maka man feel you worka cheap; maka him feel you good doc, geta good price; worth more you ask.'

To Tony goes the medal for a bit of homely philosophy which every physician would do well to memorize.

EDITORIALS

Unfavorable Signs

Even friends of the Federal social security program are beginning to question the wisdom of the national old age and unemployment insurance act in its present form. Administrative details are still in an embryonic stage but it is already apparent that the execution of this law will be surrounded with voluminous red tape requiring the creation of an extensive bureaucracy. The cost of this will necessarily come out of the pockets of industry, labor and the consuming public; and every one must pay, whether he stands to benefit by the measure or not.

Besides endangering the standards of medical care, the adoption of compulsory health insurance would intensify the objections raised against the old age and unemployment laws. It would mean still higher taxes and living costs, the extension of bureaucratic control over American life and, to an even greater degree than current social security legislation, taxation of the entire nation for the benefit of a small percentage of the people.

While it is too early to pass judgment on the old age and unemployment insurance act—before even it is in operation—there are many indications that it will fall short of the hopes held out for it. Experienced actuaries say that the funds obtainable at present rates will be insufficient to provide the promised benefits

under adverse conditions. There are more serious signs that the law may defeat its own purpose in the avowed intention of several large employers of labor to increase mechanization of their plants in order to diminish payroll taxes. Additional levies for compulsory health insurance would spur the replacement of men by machines.

It will take a number of years for the economic organization of our society to adapt itself to the new conditions imposed by obligatory old age and unemployment insurance. At this time it is not possible to predict when the adjustment will be completed or whether the benefits will be commensurate with the costs. Until the nation has had an opportunity to evaluate the social security measures already in force, it would be high folly to add compulsory health insurance to its burdens and destroy the system of private medical practice which has functioned successfully in good times and bad because of its freedom from political and industrial control.

Stop Them Now

A sharp revival of chiropractic activity all over the state lends credibility to a rumor that the spinal manipulators are about to launch another campaign for legislative recognition. Past experience has demonstrated that the chiropractors are masters of legislative lobbying. With millions at stake, they are willing and able to spend enormous sums in propaganda for their cause.

The time to stop a possible chiropractic drive is now, before they have had time to organize a legislative bloc in their behalf. It is a number of years since Albany has had a chiropractic licensing bill up for consideration, and some of the newer members of the Legislature have had no occasion to ascertain the falsity of the claims made for this cult. Some old timers will remember the anatomical demonstrations in committee which effectively exploded the theory of chiropractic. However, the defenses of the past cannot be relied on for the present; and physicians in every part of the state should immediately communicate with representatives at Albany to warn them of the consequences of recognizing an irregular cult with no sound basis in scientific fact or principle.

The Medical Practice Act of this state has been widely heralded as an example of the educational safeguards with which enlightened law-makers surround the practice of healing. There is nothing in the theory or methods of chiropractic that could be incorporated in the curriculum of an authentic school. If legislative recognition were granted to this irrational system, it would create an irreparable breach in the educational defenses of medicine through which other dangerous and worthless cults could easily follow.

Comparisons Are Instructive

There is an old gag which was current some years ago which we dare to repeat. An ambitious rooster, having wandered a bit from his fireside, watched a female ostrich with wonder and amazement, when she clucked her notice to the world that she had laid an ostrich egg, he stared and stared at its size and extent. Wanting to do something, desiring that his own females might at least *try*, he crowed and called them around him, and said, "Far from criticizing you, ladies, I

simply want you to look at what others are doing! Can you not try to do likewise?"

The story has point when one listened to the inaugural address of Dr. Charles E. Farr, when he was inducted as President of the Medical Society of the County of New York. Commenting on the problems presented to organized medicine for solution, he deplored the limited financial contributions which the members of the Society paid to the general funds to enable men to give their time and best efforts toward achieving results desired by all of We pay but a small yearly item for the large amount of work needed. Quoting from labor units. Dr. Farr said that a hod-carrier earns \$7.40 per day. pays \$24 a year dues, plus \$0.75 for each day he works. Assuming that he works 200 days a year, he earns \$1,480 a year, and on this basis he would contribute \$174 to his organization for the protection of a daily earning of \$7.40. A bricklayer draws \$13.00 per day. He pays to his organization \$48.40 per year dues plus \$1.50 for each working day. Assuming that he works 200 days a year, he will earn \$2,600.00 a year and from this he pays to his organization a total of \$348.00 for the protection of that income. "How pitifully insignificant is the \$10.00 dues paid by the doctors of this State to their State organization for the protection of their economic security," says Dr. Frederic E. Elliott, the Chairman of our Committee on Economics, in commenting on these figures.

When we consider that the workmen's compensation law will demand a real man's best labors; when we begin to envisage other activities in which we must engage to protect the public against itself and for the general welfare, and when it is realized that the haphazard work of men busy in private or institutional medical practice is inadequate and inefficient to meet the needs which the present era has brought on us, and which will impose increasingly heavy demands, we are unabashed in calling upon the profession "to look at what others are doing"

and to echo the remark, "Can you not do likewise?"

It is time to consider our needs, enlist an adequate working force, while remembering that the "laborer is worthy of his hire" and make financial provisions to meet the situation.

The Waldorf-Astoria Session

The plans for the scientific meeting of the State Society are rapidly taking shape.

Dr. James' exhibit, which comes to us from the Army Medical Museum in Washington, is of unusual interest. Amebic dysentary is of importance even to those of us who are not practicing in the tropics.

The first day's session of the section on Medicine will be devoted to a Symposium on Arthritis, the speakers being from the leading group of those particularly interested in the treatment of this important disease group. The Wednesday session comprises a group of papers on the most recent progress in endocrine therapy.

A guest speaker will appear in the Section in Obstetrics; Dr. H. H. Ware of Richmond, Virginia, who will speak on "Full Term Uterine Pregnancy."

A group of researchers in Philadelphia headed by Dr. L. G. Rowntree for a considerable period of years has been studying the role of the thymus and the pineal glands in growth and development. Their work has reached such practical conclusion as to permit them to make an outstanding exhibit at the 1935 meeting of the American Medical Association, winning the silver medal. Dr. Rowntree will present some further developments of this work before the Pediatric Section, his topic being "The Role of the Thymus Gland in Growth and Development, an Experimental Study." This paper will be correlated with a scientific exhibit. Another endocrine paper "Hypogonadism and Cryptorchidism" by Dr. M. B. Gordon of Brooklyn will be correlated with a scientific exhibit.

The new Section on Industrial Medi-

cine, under the direction of Dr. Hitzrot, contemplates devoting their first day program to the industrial medical question of the day, Silicosis; and the April 29 session to dermatoses, infections, tendon, nerve and bone injuries of the hand, the industrial worker's best tool and therefore the industrial surgeon's greatest responsibility.

The entire first day in the Dermatology Section will be devoted to the different manifestations of allergy, going into the multitudinous causes thereof, food, fungi, drugs, including the relation of general allergy and general disease conditions to skin manifestations. A study on experimental work on bismuth by mouth in the treatment of syphilis will be presented by Dr. Charles R. Rein and Dr. Marion Sulzberger of New York.

The closer and closer interrelation of the x-ray with clinical diagnosis is shown by Dr. L. W. Gorham of Albany in his paper on "Differential Diagnosis Between Coronary Occlusion and Pulmonary Embolism" in the Radiology Section Program. Studies of the bone manifestations of Hodgkin's Disease by Dr. Samuel George Schenck of Brooklyn will be accompanied by a scientific exhibit, and other exhibits will be correlated with the program.

In the Public Health Section, Commissioner Parran of the New York State Department of Health will speak of the League of Nations Public Health programs as contacted by him in his recent visit to Geneva.

As the details become completed we shall refer to this program again. We are indeed fortunate in the matter of the Chairmanship of the Committee on Scientific Work. Dr. William A. Groat has merited the confidence reposed in him and has accepted his responsible post, as a job to be well done. Say what you will of other factors which draw and interest the medical profession, but one fundamental must never be lost to sight. The profession is anxious to learn more of medicine, and wherever a program is provided that gives them what they think

they can translate into practice, there they will come.

The program offered augurs for a well attended and enthusiastic meeting in New York City in April.

· Distinguished Guests

Among the distinguished guests who will take an active part in the annual session of the State Society in April, is Lord Horder of Ashford, K.C.V.O., M.D., D.C.I., F.R.C.P. of England.

Baron Horder is a man of exceptional attainments and interests. He is senior physician to St. Bartholomew's Hospital in London. He is the Consulting Physician of the Cancer Hospital. He served his country during the World War in the Army. He has held many positions of honor and executive grade. He is an ex-president of the Harveian Society of London: President of the National Birth Control Association; Executive Chairman of the Advisory Scientific Committee, British Empire Cancer Campaign. Member of the Governing Body of the British Post-Graduate Hospital. President of the Medical Society of London, and other societies and hospitals.

His work on clinical pathology in practice is known here, in addition to which he is a contributor to contemporary English medical literature.

Lord Horder will address the general assembly of the Society and also the section on Medicine.

We are glad to extend welcome and assure him a gracious reception while among us.

Another distinguished visitor is Dr. William M. James of Panama. He is connected with the research going on in both the Gorgas Memorial Institute and the Matias Hernandez Asylum. Dr. James brings us the latest on the topic of amebiasis. The subject will be dealt with as a form of colitis, demonstrating the necessity of treating this infection as a colitis. The reasons for the failures of many so-called specific treatments will be shown, and the reasons underlying the

relapses which occur will be explained. Collaborating with him, in both demonstrations and explanations will be Dr. J. M. Lynch and Dr. Hakaussn, proctologists. Dr. C. M. Johnson, the consulting protozoologist of the Gorgas Memorial Institute, will show an almost fool proof method of stool examination, and Dr. Getz will demonstrate pathology.

In telling of these visitors and indicating what they will do, it is not our intention to elaborate the scientific program but rather to indicate how worthwhile, from a standpoint of scientific study value, the ensuing meeting will be.

Status of Short Wave Therapy

Physiotherapy has been employed as a therapeutic agent for countless centuries. The beneficial effects derived from the massage of sore muscles, the bathing of wounds, and lying in the sun were evident to the earliest humans. In recent years, the impetus attained by the immense amount of research concerning the value of light and heat in the treatment of disease has disclosed new physical measures, the therapeutic values of some of which are not understood thoroughly as yet.

The newest of these are the short and ultra-short wave diathermy. The former comprises wave lengths ranging from twelve to thirty meters. It has been definitely determined that in their clinical effects, these wave lengths differ but little from ordinary diathermy.1 The ultrashort waves which are used medicinally have wave lengths which are below twelve meters. The method of applying the heat from the ultra-short waves and the range of clinical application differ definitely from diathermy. Full recovery without recourse to surgery has been reported from the use of ultra-short wave therapy for carbuncles, empyema, pulmonary abscess and acute pelvic inflammation.2

¹ Kovacs, R.: Electrotherapy and the Elements of Light Therapy, 2nd Ed., Phila., 1935.

² Turrell, W. J.: Short Wave Therapy, Arch. Phys. Therapy, X-ray and Rad., 16:5, 1935.

Despite the encouraging clinical reports, short wave therapy is still in its experimental stage and should remain, for the present, strictly in the province of the The regulation skilled psysiotherapist and the control of dosage is still a crude procedure since the milanimeter will not show the amount of energy which is flowing through the patient. The operator of a short-wave machine has no definite means of judging when the skin and deeper parts are being heated excessively Consequently there is great danger of subjecting the patient to skin burns, hot spots, and coagulation of subcutaneous tissue 3 Furthermore, there is no definite standard for the manufacture of a shortwave apparatus Until further clinical and experimental studies have been made, the employment of this type of physical therapy should not be undertaken by anyone not trained in the use of physical agents

Trichomonas Vaginitis. A Venereal Disease?

The trichomonas vaginalis, a flagellate protozoon which is capable of producing a protracted vaginitis, has been the subject of much study in late years. The disease it causes is characterized by a profuse, foul, greenish discharge, pruritis vulvae, and intertrigo. The protozoon is easily identified on smear.

There has been considerable speculation as to why this ordinarily harmless parasite, which frequently is found in the normal vagina, should assume sudden pathogenic activity. According to Allen, Jensen, and Wood¹ a symbiosis must occur between the trichomonas and a green-producing streptococcus before the former will assume virulency. The streptococcus they have isolated shows a different electrical grouping from the other streptococcus which normally inhabit the vaginal tract.

Of still further interest are the results obtained by Allen et al from their studies of the male contacts of several women who had a trichomonas vaginitis. Seven had a chronic prostatitis, and from the prostatic secretion they were able to isolate a streptococcus which had the same electrical reaction as the streptococcus found in the vagina. In six instances the trichomonas itself was found in the prostatic secretion. Nothing was found in three.

These observers feel that trichomonas viginitis and prostatitis are to be regarded as venereal diseases and that sexual intercourse is the most likely means of transferring the infection. The evidence thus far is too scant for a complete acceptance of their conclusions, but their findings suggest further study into the nature of trichomonas infections.

Oxygen Administration

The usefulness of oxygen as a therapeutic agent in pneumonia is acknowledged. The oxygen tent and the equipment necessary to administer it leave much to be desired. The most important item in the set-up, of course, lies in the necessity that there be a proper oxygen concentration within the tent and that there be the minimum amount of leakage.

A number of oxygen tent manufacturers have sold tents alleging that it is unnecessary to test the oxygen concentration provided a steady flow of between seven and twelve litres per minute is maintained. But faulty administration may nevertheless be present. In some instances the tentage leaks to a degree that even if the recommended flow is established, there will still be a concentration of less than thirty per cent.

The remedy is apparent. The physician's prescription should not call for the application of an oxygen tent, but for a given concentration of oxygen available to the patient. The use of a nasal catheter, or the introduction of a catheter into the oral pharynx should be ordered for lesser concentrations. The oxygen content of

⁷ Krusen, F H Short Wave Diathermy, J A M.A 104 1237, 1935

¹ Allen, E Jensen L B, and Wood, I H Amer J Obs and Gyn, 30 565 and 30 736, 1935

the tent in use should be tested and the concentration employed noted. Authorities have declared that at the present time it is safe to say that over ninety per cent of the oxygen tents in use in the country are not tested for oxygen concentration.

The factors which we have stressed become still more important when heliumoxygen is used therapeutically. There is need for the determination of the amount of helium-oxygen atmosphere in the tent.

We feature these facts because of their timeliness in the pneumonia campaign which is going on, and also because we are desirous of having oxygen therapy properly administered. To rely on a therapeutic agent, and have its usefulness negated by failure to administer it properly is hardly good medicine.

We hope that some one will develop a method of automatically recording the oxygen atmosphere in the tents while they are in use. Two things would thus be accomplished. It would note and also prevent waste, and secondly, our patient would receive the dosage which the physician prescribes for him.

CURRENT COMMENT

HENRY FORD, interviewed by Samuel Crowther in the Saturday Evening Post of February 1, 1936, speaking on "The Only Real Security," among other things said, "Our forefathers came out of Europe to pioneer in a new land, not because the old country gave no further opportunities for pioneering but because the working of customs and governments had denied to the common man the liberty to use the opportunities that were about him. We here have had the liberty to pioneer. Our great pioneering has not been in the covered wagons, but in the laboratories and workshops and in better ways of living together as a human society." "Today, as always, there are those who believe that the mental. as well as physical map has been completedthat we know all we are ever going to know and that our job is henceforth to rearrange and reorder what we already have. That is the Old World spirit. That is the surrender of those who fear to think, to plan and to try. We left all that behind more than three hundred years ago. We are not willing to saddle America with Europe's fallacies and failures. And it is remarkable

how many of them have been offered for our acceptance."

RECENTLY HARMAN, in the British Medical Journal of October 6, 1934 (supplement) studied the question as to the efficacy of opticians' and optometrists' examinations of the eyes of persons coming under their care.

The report, based on 10,085 cases, showed that sixty-four per cent had errors of refraction only. Twenty-nine per cent had in addition "other eye conditions," and nearly six per cent had no errors in refraction at all. The National Ophthalmic Treatment Board's figures were also studied. This Board showed that many patients did not require glasses at all. There were 68,044 patients examined by 821 physicians. Slightly more than six per cent did not require glasses.

Harman concludes "that opticians did not recognize the defects present in the eyes of the patients seen by them, or if they did recognize them they did not report them for medical examination. * * Patients who go to opticians to have their sight tested do not get what they ought to get."

In view of the efforts of the optometrists in this State to extend their sphere of activity this study should prove interesting to our profession, and to the public.

FROM THE REPORT of the Committee on Economics of the Medical Society of the County of Monroe, and the Rochester Academy of Medicine, as published in the January, 1936, issue of their Bulletin, we find the following: "The trend in medical economics continues to be an attempt to hold the advantages of individual private practice, and to obtain the advantages of socialized practice-that is, to maintain the right of the sick and wounded to freedom of choice of physician; to wit, the new medical chapter in the compensation law; and, at the same time, to establish the physician's rights to remuneration for his services rendered those who cannot pay for it themselves. Although there is a definite improvement in economic conditions, there still remains a great demand for service, and a great many physicians ready to render it, but the one does not adequately support the other. This condition is not limited to the field of medical economics. The farmer has suffered a sixty-three per cent reduction in selling value of produce, but has reduced his quantity production only six per cent. In other words, he is doing about the same amount of work he did fifteen years ago, for half of the return he then had. The manufacturer, on the other hand, has reduced the prices of his products only six per cent,

but has reduced his production eighty per cent. In other words, he has fixed his selling price at a profitable level and has held it there by creating a demand for his

product

Medical service is a fundamental necessity of life. Price fixing, by refusing to render service except for a price is impossible. Our profession is bound by laws of human necessity to render service in bad times as well as in good. An immediate solution of our economic problem lies in the wide-spread payment of adequate wages to the employed group. If people earn money, there are enough who pay to keep us going. We all go up together."

THE EDITOR of the St Louis County Medical Society Bulletin of January 17, 1936, comments on the recent broadcast over the Red network of the National Broadcast ing Company when the question of State Medicine was debated. The editor's comments are particularly addressed to Mr Bower Alv an educator who took part in the broadcast and likened the proposed socialization of medicine (State Medicine) to the State's control of education pertinent examples from the local field where he evidently is at home and is cognizant of conditions, Dr Clyde P Dyer said, wonder if it would not be more fitting for a public educator like Mr Bower Aly, who was one of the debaters to debate the subject, 'Resolved that the several states should enact legislation providing for a system of complete educational service available to all citizens at public ex

"I would like to ask Mr Aly if he recognizes and is making any real effort to enable the many millions of boys and girls who would like to continue through High School, College or University Under the present educational system, education is not free or available at state expense but must be paid for by the individual or their parents in addition to the school taxes that they now pay This is true not only in the University of Missouri where there is tuition and books and board that cost the individual \$400 or more a year, but even for high school education. In St Louis County and throughout the state of Missouri there is at present a most inadequate system as well as inadequate delivery of the present system of education. Why not recognize this great need as it is very closely connected with what Mr Aly later said was the really basic reason 'That we have been lacking in America a belief in the dignity and worth of American citizenship' And again later he said 'Oh my friends, we Americans must develop for ourselves a new idea of American citizenship. Education and more education will develop more American citizenship, and state medicine will not be a

contributing factor

'To quote from the St Louis Globe Democrat of December 15, 1935, regarding education in St Louis County In 1928, when Supt Bascom of the Bryless School District started a minth grade with eleven pupils in one of the grade school buildings a state high school inspector came looked over the situation shook his head dolefully and expressed grave doubts of the advisability of trying to extend the educational opportunities of the district

"The Bayless School District, six miles square, with a present school census of approximately 700 children, is one of the oldest in the state antedating the civil war

'It was a heart breaking choice in former days when I (Supt Bascom) had to select the two children from the eighth grade who were eligible to take the competitive examinations for free high school scholarships offered in St Louis County

"There were so many who ought to have had the same chance. And sometimes those who won such scholarships were unable to

take advantage of them?

And this is the educational situation in our prosperous well populated country, which has just built a new high school that

it is justly proud of

What it is out in the rural districts of the state I must leave to your imagination and the political set up of educational men of Missouri are to blame for allowing it to continue. What a work for Mr. Aly and the other educators to clean up, as this situation is not only in Missouri but it is in every state and school district of the United States, after mun, many years of effort toward education.

"There is need for better delivery of adequate medical service to all people but state medicine will not deliver it as well as the present system will if allowed to adjust itself to the times and people of various

localities

If Mr Aly would devote his time and efforts to lifting education out of the very unsatisfactory condition that it is in, he would be doing work that he is educated for pud for and is or should be concerned with But he also might know that the political set up of the educational system in Missouri is such that it is not possible for him to change or correct all of these things so that adequate education would be available to all citizens at public expense but medical men do not condemn the entire educational set up, because of its inadequacy or inefficiency

"Neither would it be possible for a few socially-minded practitioners of medicine, economists and professors to set up a system that would not be full of 'political dictation,' inequality of service as at present, wasteful taxation, increased death rate and many as yet unknown evils.

"Mr. Aly would resent a small group of less than one per cent of the educators trving to tell the other ninety-nine per cent that the present educational system was entirely wrong and that they wanted to throw the system aside and start a new system modeled after Russia, or other European Countries this democratic country where the

majority usually control.

"To summarize I would say that it seems there is so much to correct in the present educational system that Mr. Aly and our educators would be doing the greatest service to the greatest number by correcting the evils of inadequate education at present under public expense in part, and not interfering with the medical problems of which he and they know so little."

THE EDITORS OF Today, in the issue of February 1, 1936, say, "In 1900 there were only 262 beauty shops which did a business of \$7,000,000 a year, now there are 30,000 and they gross \$200,000,000."

Which is a thought provocative enough. Each can think it out for himself when he

considers medicine.

THE STATE CHARITIES AID ASSOCIATION publishes in its January News the recommendations of the Wardell Commission. The report has been submitted to the legislature with the endorsement of Governor Lehman.

As to State policies and reorganization, the principal recommendations were:

1. The State should adopt a permanent policy of paying a substantial part of the cost of home relief administered by the local governments. For the year 1936, the State aid should be at least forty per cent and should be de-termined by the Legislature from time to time in light of future conditions.

2. The allotment and control of State funds should be placed in a reorganized State Department of Social Welfare with power to exercise the necessary supervision and control over

expenditure of State funds.

3. After July 1, 1936, the State Commissioner of Social Welfare should be appointed by the Governor instead of by the State Board of Social Welfare, and should be given full administrative responsibility for the functions placed in the State Department of Social Welfare.

4. The present Board of Social Welfare, which is now the administrative head of the Department of Social Welfare, should, on July 1, 1936, be replaced by a non-administrative

Board, appointed by the Governor, with the advice and consent of the Senate. Instead of twelve members appointed for eight-year terms, on a geographical basis, the Board should consist of eight persons appointed for overlapping terms of four years. The Board should make the rules and regulations in respect to the public assistance administered under the supervision of the State Department and for all private institutions and agencies now subject to its rules. It should carry out its constitutional function visitation and inspection of charitable, eleemosynary, correctional and reformatory in-stitutions. It should act as a board of review to decide appeals by any officials or agency from an administrative ruling or decision of the Commissioner of Social Welfare.

5. Contingent upon the enactment into law of the preceding recommendations, the powers and duties of the T.E.R.A. in relation to home relief should be transferred to the State Board, and the State Department of Social Welfare on January 1, 1937. The T.E.R.A. should be continued until February 15, 1937 in order that the 1937 Legislature may determine whether the provisions of the Wicks Act, authorizing work relief, should be continued, and if so, whether such functions can best be administered by a temporary agency or a permanent State Department.

6. State aid for home relief and old age relief should be provided by advance grants to the localities with a comprehensive post-audit by State authorities, instead of the present cumbersome and unwielding system of reimbursement requiring submission to the State Office of vouchers and financial documents relating to each individual relief order or payment.

Recommendations as to Local Welfare Organization.

1. The relief functions of the towns should

be transferred to the County.

2. All forms of relief administered by the County should be paid for by the County without a charge back in the taxes levied on the place of settlement of the recipient. Funds for each form of relief should be raised by taxes levied only in the area in which the County administers that relief.

3. The County Commissioners of Public Welfare should be appointed by the Board of

Supervisors for a term of four years.
4. The County Commissioner of Welfare should have suitable offices accessible to the public and usually not located at the County Home. Because of the marked increase in the responsibility of the County Commissioner, a Superintendent of the County Home should be appointed, and the County Commissioner should not be required to live at, or on the premises of the County Home.

5. Salaries of the Commissioners of Public

Welfare, both city and county, should be adjusted in many localities in order to attract

persons of suitable qualifications.

ACCORDING TO THE New York Sun of January 21, 1936, Daniel C. Roper, addressing the National Retail Dry Goods Association, said: "After declaring that the profit and loss system of American business must be maintained and must be assured general channels of constructive progress," Mr. Roper said that 'poor housing for a nation such as ours breeds discontent; good housing fosters social stability."

"A home building program to assure activity over a ten-year period was advocated by Mr. Roper as he drew a picture of mass production of dwellings comparable

to the motor car output. He said:

From the viewpoint of social objectives, we cannot undervalue the importance of placing as many American families as possible in homes which they can purchase for a reasonable price and maintain through a fifteen or twenty year period of equitable financing.

"'Pride in home ownership and the cultivation of the virtues enhanced by that environment is a sine qua non to the safety of our form of government and sustained

happiness of the people."

THE EDITORS OF Today of January 25, 1936, among other things say, "The search of frightened money for a cyclone cellar is a thing of the past, but the accumulation of savings through thrift has not begun on an important scale. We deduce this from the condition of the mutual savings banks of New York State, which were once, and probably still are, an excellent index. Their deposits at the beginning of 1935 were \$5,153,357,083, and at the end of 1935, \$5,186,547,393. The increase is \$32,190,310, but that is \$100,000,000 less than the deposits would have grown to if they had merely been left undisturbed, at 2 per cent compounded quarterly. Therefore, net, no new money has been deposited either by people of means who used mutual savings banks as a kind of hoarding device during the depression, or by the thrifty wage earners whom the system is intended to serve."

THE Saturday Evening Post of January 25, 1936, carries the following editorial on

Compulsory Health Insurance:

"Many social workers, actuated by the best of motives, have long been pressing for compulsory health insurance, with free medical attendance included. It touches our pride as well as our compassion to hear of folk in the richest country in the world without proper care when they are ill because they are too poor to pay for it. These feelings are intensified when we are told that nearly half of our population gets no medical attention whatever.

"If these hardships could be done away with by setting up a system of state medicine, that would be a powerful argument in its favor. Unhappily, the experience of nations which have given such systems a thorough try-out is anything but encouraging.

"According to a study of conditions in England, in 1933, made by the London Times the time lost through sickness by insured workmen averaged twelve and onehalf days per man yearly, an aggregate of twelve months' work for 558,000 persons. Before compulsory insurance went into effect, the loss was only nine days: the increase under the insurance scheme being more than thirty-eight per cent. Germany has had half a century of experience with insurance against sickness, and in those fifty years the time lost through illness has trebled. The comparison with American figures is striking, for the average loss of time by our own workmen is only about six and one-half days a year, and the figures have been stationary at that level for a quarter of a century.

"We are indebted to Dr. Frederic E. Sondern, president of the Medical Society of the State of New York, for a well-rounded study of the whole matter. To quote his own words: 'We are asked to occupy our lives with false gestures of administering good medical care which the conditions will not allow us to give; we are asked to make ourselves a part of a gigantic bureaucracy and play politics with human

lives.'

"The most significant paragraphs of Doctor Sondern's study are those which deal with our growing reliance on group action. He, like most Americans, believes that our national destiny lies in individual rather than in collective efforts, and he does not fail to point out that one of the most powerful factors which brought into being the Renaissance period of the fourteenth century was the realization by men of their own individual powers and of the responsibilities those powers carried with them. This was one of the prime characteristics of the great eras of history.

"Doctor Sondern does not overstate the facts when he says that 'we have evidence of retrogression in the increasing domination of the group spirit, the sacrificing of individual independence, a lessening sense of personal responsibility and a growing paternalism, the former intrepid pioneer in thought and act leaning more and more on

the soft bosom of the state."

THE FOLLOWING is from the Jackson County Medical Journal of Kansas City, Missouri: "Much has been written and spread by means of the printed sheet and by word of mouth about socialized medicine.

By far the greatest part of it for lay consumption has been the product of social reformers because medical men have been reticent about publishing their own ideas to the world at large for various and sundry reasons. They have expressed themselves chiefly through the medium of their own scientific journals or at private forums. Much of the little that has been permitted to seep out to the laity has been couched in such exacting language and with such detail that it has been lacking both in appeal and in comprehension to all but a few of those whom it was intended to impress.

Officers—President, Dr. S. M. Strong, 42-33 Kissena Blvd., Flushing, N. Y.; Vice President, F. H. Hoyt, 4250 Cross Island Blvd., Bayside, N. Y.; Historian, Thomas B. Donaldson, 18 Washington Place, Newark, N. J.; Secretary and Treasurer, D. A. Woodhouse, 156 Chambers Street, New York City. Directors—James Madden, 40 Church St., Paterson, N. J.; Theodore Van Wyck, Lynbrook, L. I., N. Y.; A. Clinton Wilmerding, 16 John Street, New York City; Capt. M. W. Collyer, Chelsea on Hudson, N. Y.; Moses Tanenbaum, 521-5th Avenue, New York City; F. P. Trautmann, 15 Park Place, New York City; J. E. Algeo, 2523 Aqueduct Avenue, New York City.

To the Editor:

In the spring of 1888 New York City and the surrounding country for some distance was visited by the heaviest and most noted snow storm in the memory of our present people. The onset was sudden and unexpected, the wind velocity terrific, which piled the snow against the building of all types to the depth of many feet, and in the more open spaces, drifts were made that in places were perhaps twenty feet high and are said in parts of Long Island to have been above the carriage tops two months after the Below the earth's surface tragedy was also felt, as the wind filled many of the wells in the country sections, causing a shortage of water in many of the homes, and the cold was severe, so severe that the Hudson and East Rivers were frozen over and people walked across the East River because the storm had stopped every form of transportation except the indomitable feet of man, who plod through and dug through drifts while his strength lasted -and then-well, the deaths in New York City numbered about 400.

Railway men, lawyers, boatmen, sailors, business men, teachers, newsboys and many others have written the stories of their personal experiences, which, collected together have made new and deeply interesting pages of history of our Great Blizzard, but so far only a very few of our physicians have added their experiences and certainly

no storm ever kept our doctors from the bedsides of the needy sick and there must be many a thrilling story of the doctors' struggles, both by day and night, through this storm, that should be added to the history now being written by individuals of their personal experiences and what they saw and knew of the then existing conditions in 1888

It happens that in 1929, Mr. John Gilleran, lawyer of New York City, and Mr. Theodore Van Wyck of Valley Stream. Long Island, met and talked together of this great storm and they decided to try and locate other survivors of this blizzard. The word spread, a newspaper made an announcement of a few lines, telling of the proposed meeting, and later that spring, twenty-nine survivors met at Mr. Gilleran's office, renewed old acquaintance and reviewed their personal experiences. I happened to be among those at this first meet-A little social organization was proposed and Mr. Van Wyck was elected our First President and I was among those elected to the Board of Directors.

Today this little organization has developed into a real businesslike historic society, which from its inception has been known as "The Blizzard Men of 1888." The word "Men" in this title refers to mankind, for the society has many women members and is by no means limited to male members. have adopted as our real reason for existence the collection of the individual accounts of experiences, which when added together give a history of this Great Blizzard. Nothing like it has heretofore been written, so that for the first time the real history of this storm, together with many of the details of the existing conditions and the personal customs of our people at that time are coming to light in a very interesting and instructive fashion. As these stories come to us, together with old letters, pictures, newspapers, etc., we are delivering them all to the New York Historical Society for safe keeping, and when damaged,

papers are being repaired, and all are available to the public for reference.

We beg now that the personal experiences of our doctors while attending their sick be written by each individual and submitted to our Secretary and Treasurer, Mr. D. A. Woodhouse, 156 Chambers St., New York City. We would of course welcome all those who had experiences in this blizzard and survived to become members of "The Blizzard Men of 1888" and thus add their names to the now good-sized list of survivors, among whom appear the names of some of our country's most distinguished-citizens.

Doctors, we need your stories to make this chapter in history complete. Our next meeting will be a luncheon at the Hotel Pennsylvania, New York City, at noon on March 12, 1936.

S. M. STRONG, M.D.

February 1, 1936

American Association for the Study of Goiter

To the Editor:

The American Association for the Study of Goiter again offers the Van Meter Prize Award of \$300.00 and two honorable mentions for the best essays submitted on the goiter problem. This award will be made at the discretion of the Society at its next

annual meeting to be held in Chicago, Illinois, on June 8th, 9th, and 10th.

The competing manuscripts, which should not exceed 3000 words in length, must be presented in English and a typewritten double spaced copy sent to the corresponding Secretary. Dr. W. Blair Mosser, 133 Biddle Street, Kane, Pennsylvania, not later than March 1, 1936. Manuscripts received after this date will be held for competition the next year or returned at the author's request.

The Committee who will review the manuscripts is composed of men well known in the fields of research and clinical investigation of problems related to the thyroid gland. This Committee did not consider any of the manuscripts submitted at the last annual meeting to be of a calibre to justify the award, and consequently the award for the year 1935 was withheld by the Association.

The Association will publish the manuscript receiving the prize award in their annual Proceedings, and reserve a place on the program of the annual meeting for presentation of the manuscript by the author, if it is possible for him to attend. This will not prevent its publication, however, in any journal selected by the author.

Very truly yours,

W. BLAIR MOSSER, M.D. Corresponding Secretary

November 29, 1935

NOTICE OF EXAMINATIONS

The American Board of Obstetrics and Gynecology makes the following announcement:

The next written examination and review of case histories of Group B applicants (candidates specializing for less than ten years) for certification by this Board will be held in various cities of the United States and Canada on March 28, 1936. Group B applications must be filed in the Secretary's office not later than February 28.

The oral, clinical and pathological examination of all candidates for certification by this Board will be held in Kansat City on May 11 and 12, 1936, immediately prior to the scientific session of the American Medical Association. Applications for Group A candidates (those specializing for ten years or more) must be received not later than April 1, 1936.

The annual informal dinner and general conference of Diplomates attending the American Medical Association convention will be held at the Hotel Kansas Citian, Kansas City, Missouri, on May 13, at 7:00 P.M. At this dinner the successful candi-

dates from the examinations of the two preceding days will be presented in person, and short addresses will be made by several members of the board.

For further information, booklets, and application blanks apply to the Secretary, Dr. Paul Titus, 1015 Highland Building, Pittsburgh (6), Pennsylvania.

We are graduating as many persons from the community into nervous and mental hospitals as we are sending out into the community each year from our colleges and universities, according to the National Health Council. More than fifty per cent of all hospital cases in this country are those of some form of mental illness. The present annual average of mental cases recovered or improved is about forty per cent.

Doctor, to small boy: "Sit down, sonny, you have shown good manners long enough.

Small Boy: "It isn't good manners, doctor, it's a boil.—Bulletin of the Medical Society of the County of Monroe.

Society Activities

General Committee of Arrangements

The General Committee of Arrangements for the coming Annual Meeting of the Medical Society of the State of New York is as

Dr. Frederic E. Bondern, President, Medical Society of the State of New York. Dr. Daniel B. Dougherty, Secretary, Medical Society of the State of New York. Dr. Charles E. Farr, President, Health Society of the County of New York. Dr. Milton J. Goodfriend, President, Medical Society of the County of Bronx. Dr. Henry Joachim, President, Medical Society of the County of Kings. Dr. James Matthew Dobbins, President, Medical Society of the County of Queens. Dr. Wm. C. Buntin, President, Medical Society of the County of Richmond. Dr. Arthur J. Bedell, Past-President, Medical Society of the State of New York. Dr. Peter Irving, Asst. Secretary, Medical Society of the State of New York. Dr. Samuel J. Kopetzky, Speaker, Medical Society of the State of New York. Dr. John A. Hartwell, Director, New York Academy of Medicine. Dr. David J. Kaliski, Chairman, Coordinating Committee. Dr. William A. Groat, Chairman, Committee on Scientific Work. Dr. William A. Krieger, Chairman, Committee on Scientific Exhibits. Dr. Chas. Gordon Heyd, Chairman, Committee of Arrangements.

The 131st Annual Meeting of the Medical Society of the State of New York will be held in New York City, April 27, 28, 29

and 30, 1936.

The House of Delegates, the Scientific Sessions, the Scientific Exhibits and the Commercial Exhibits will all be held at the

Hotel Waldorf-Astoria.

It is requested that the members contemplating visiting New York City for the Annual Meeting will make their reserva-tions with the Waldorf-Astoria early as the Hotel Management is making a reduction to members of the Medical Society of the State of New York and the hotels in New York City will be crowded at that time.

The Annual Banquet will be held on Tuesday evening, April 28, at seven-thirty p.m., in the Grand Ball Room of the Waldorf-The Committee on Arrangements are fortunate in having as their guests Lord Horder, Chief of the Medical Department of St. Bartholomew Hospital, London, and Dr. Willard C. Rappleye, Dean of the College of Physicians and Surgeons, Columbia University, New York City.

The attendance at the Banquet will be limited to one thousand. At the 1933 Meeting there were over eleven hundred guests and the Committee have thought it wise to limit the number to one thousand so that overcrowding may be avoided.

An interesting feature of the Annual Meeting will be the Open Forum on Wednesday evening, April 29, at eight-thirty p.m. in the Grand Ball Room of the Waldorf-Astoria. This Meeting will consist of eight 12 minute addresses by distinguished clinic-

ians on the following subjects:

What the Community Should Know About: 1. "Quacks and Quackery". 2. Diabetes. 3. Why People Die of Appendicitis. 4. Stuttering and Stuttering Personality. 5. Failing Eyesight. 6. Goiter. 7. Infantile Paralysis. 8. Common Colds.

This Meeting is to be open to the public.

On Thursday, April 30, an all-day Clinic Day will be held in the Hospitals and Universities of Greater New York in all departments of general medicine and surgery and the specialties.

Between one and two p.m. on Wednesday, April 29, the Program of all of the listings of Hospital Clinics will be distributed at the Registration Booth of the Society in the Foyer of the Ball Room of the Waldorf-Astoria.

Preceding the Annual Meeting and during the Meeting itself numerous radio broadcastings will be made concerning the work of the Society, the scientific features and special topics of interest.

The Press Publicity Department will be situated in the Waldorf-Astoria Hotel, close to the Registration Bureau, and will be in

charge of Mr. Dwight Anderson.

The Publicity Department for the Annual Meeting is created by Resolution of the Executive Committee of the Medical Society of the State of New York and all publicity connected with the Society, its Meetings, Papers, Exhibits, shall be cleared through this Committee. Mr. Anderson shall prepare copy for release to the press and no official communication shall go from the members appearing on the programs except through this Committee.

HOSPITAL COMMITTEE ON CLINIC DAY

Dr. R. H. Kennedy, 115 East 61 Street (Beekman Street Hospital). Dr. Russell Patterson, 135 East 65th Street, (Bellevue Hospital). Dr. Louis Hauswirth, 7 East 87th Street, (Beth David Hospital). Dr. Julius J. Hertz, 55 East 86th Street, (Beth Israel Hospital). Dr. Eugene Froelich, 28 West 74th Street, (Cancer Institute). Dr. Milton A. Bridges, 580 Park Avenue, (Correction Hospital). Dr. Alexander Nicholl, 50 East 72nd Street, (Fordham Hospital). Dr. Frederick C. Holden, 59 East 54th Street, (French Hospital). Dr. S. Nordeman Weber, 150 West 87th Street, (Gouverneur Hospital). Dr. A. J. Beller, 1155 Park Avenue, (Hospital for Joint Diseases). Dr. H. H. Tyson, 20 East 53rd Street, (Knapp Memorial Eye Hospital). Dr. Walter P. Anderton, 59 East 77th Street, (Knicker-bocker Hospital). Dr. De Witt Stetten, 850 Park Avenue, (Lenox Hill Hospital). Dr. Kirby Dwight, 1045 Madison Avenue, (Lincoln Hospital). Dr. Arthur Bookman, 25 East 77th Street, (Montefiore Hospital). Dr. George E. Milani, 2021 Grand Concourse, Bronx, (Morrisania Hospital). Dr. S. S. Oppenheimer, 124 East 61 Street, (Mout Sinai Hospital). Dr. Robert F. Traut, New York Hospital). (New York Hospital). Dr. Alan deForest Smith, 410 East 57th Street, (New York Orthopedic

Hospital). Dr. J. Prescott Grant, 114 East 54th Street, (Polyclinic Hospital). Dr. W. C. White, 107 East 85th Street, (Roosevelt Hospital). Dr. E. E. Myers, Hospital for Ruptured and Crippled, (Hos. for Ruptured and Crippled). Dr. George Gray Ward, 48 East 52nd Street, (Woman's Hospital). Dr. John Henderson, 850 Park Avenue, (Post-Graduate Hospital).

COMMITTEE ON PUBLICITY

Dr. Samuel J. Kopetzky, Chairman, Dr. Iago Galdston, Dr. George W. Kosank, Dr. Clarence G. Handler, Dr. John C. A. Gerster, Dr. Louis A. Van Kleeck.

COMMITTEE ON RADIO PUBLICITY

Dr. B. Wallace Hamilton, Chairman. Dr. Iago Galdston, Medical Information Bureau New York Academy of Medicine. Dr. Floyd S. Winslow (Monroc County). Dr. James J. Borrell (Erie County). Dr. Frederick Wetherell (Onondaga County). Dr. Frederic C. Conway (Albany County). Mrs. R. S. Hirshmann (by invitation) Courtesy of New York Tuberculosis and Health Association.

Committee on Public Health and Medical Education

PNLUMONIA CONTROL PROGRAM

The Committee on Public Health and Medical Education in its annual report to the House of Delegates, presented at the 1935 meeting, indicated the need of a campaign for the control of pneumonia, to be initiated by the Medical Society of the State of New York, and to be carried on with the assistance of other cooperative groups. Such a program has been formed and is now in operation, being sponsored by the New York State Department of Health, the State Association of Public Health, the Company, the Commonwealth Fund, and the Medical Society of the State of New York.

The purposes of the campaign, briefly,

are as follows:

1. Early medical care for pneumonia patients.
2. Laboratory service for rapid type determination and other bacteriological studies.

3. Increased use of concentrated anti-pneumococcic serum, when this treatment is

indicated.

4. Adequate nursing service for all patients.

One of the important activities of the State Medical Society in this program has been the provision of controlling instruction. In December of each County Medical Society, inquiring

as to what attention the County Society had given to this program, and whether or not, it would care to have the Committee on Public Health and Medical Education provide speakers as part of the scientific program of an early meeting. A group of internists, particularly well-qualified to discuss pneumonia, and residing in various parts of the State, was organized for the purpose of giving clinical talks on pneumonia, with special reference to serum treatment. This group included the following men, all of whom have kindly consented to serve:

Dr. Morris Block, New York City; Dr. Jesse Bullowa, New York City; Dr. Russell Cecil, New York City; Dr. H. T. Chickering, New York City; Dr. Norman Plummer, New York City; Dr. Luther Warren, Brooklyn; Dr. L. Whittington Gorham, Albany; Dr. James Rooney, Albany; Dr. Charles D. Post, Syracuse; Dr. Edward C. Reifenstein, Syracuse; Dr. Wm. S. McCann, Rochester; Dr. Edward G. Whipple, Rochester; Dr. Clayton W. Greene, Buffalo; Dr. Nelson G. Russell, Buffalo; Dr. George MacKenzie, Cooperstown; Dr. Norman Moore, Ithaca.

In addition to these clinical talks, the bacteriological side of pneumonia, with a demonstration of the rapid method of typing has been discussed by some qualified bacteriologist, and in many instances the purposes of the campaign has been dis-

cussed by Doctor Edward S. Rogers, Director of the Pneumonia Control Program, in the State Department of Health, or by some member of the Committee on Public Health and Medical Education of the State Medical Society. To date, such programs have been given at the meetings of nineteen County Medical Societies, and definite plans have been arranged for meetings during the month of February in nine other County Societies. Ten County Societies will have such meetings, but have not as yet arranged for definite dates. As this program does not include the metropolitan Counties, there are only eighteen County Societies, which have not as yet made plans for such meetings. Considering the short space of time since this matter was brought to the attention of the County Medical Societies, it would seem that this record shows a fine spirit on the part of the medical profession to cooperate in this program. With the exception of three Counties, all the details in connection with these meetings were arranged through the office of the chairman of the Committee on Public Health and Medical Education.

The percentage of attendance at these meetings has been unusually high and the meetings have been marked by the interest and attention on the part of the members. The general comment of the members has been that the programs have been interesting, and the subject has been presented in a satisfactory, helpful and practical way, Already reports are reaching the Committee on Public Health and Medical Education of the successful results obtained by physicians by the use of antipneumococcic serum,

Type I, in the treatment of appropriate cases.

These activities show that the State Medical Society is well-organized to cooperate with any agencies in a modern public health program, and to bring its forces into action within a short space of time.

PNEUMONIA LECTURES

Lectures given: Cattaraugus, Cayuga, Chautauqua, Columbia, Cortland, Delaware, Genesee, Greene, Jefferson, Madison, Onondaga, Ontario, Otsego, Putnam, Rockland, Seneca, Suffolk, Tioga, Wyoming.

Lectures Scheduled

Dutchess	.February 12th

Lectures requested: Chemung, Clinton, Lewis, Monroe, Nassau, Saratoga, Steuben, Warren, Washington, Westchester.

EDUCATION OF THE PUBLIC as one phase of the campaign to reduce mortality from pneumonia in New York State was undertaken by the five organizations cooperating, the Medical Society of the State of New York, the State Department of Health, the State Association of Public Laboratories, the Metropolitan Life Insurance Company, and the Commonwealth Fund.

A three-cornered radio conversation on the subject between Governor Lehman, Commissioner Parran, and Dr. Sondern was broadcast at 6:45 p.m. on January 14, 1936, over station WGY. The following day the Governor issued a proclamation which appeared widely in the press and which was published in the last issue of the Journal [p. 198].

For the information of physicians who may not have listened in there is here reproduced the full text of the radio discussion. It gives, in proper perspective, the objectives of the campaign and the steps taken and to be taken to awake the interest of the public.

Governor Lehman: Good evening, Dr. Sondern. Good evening, Dr. Parran. I understand you want to talk to me again about pneumonia.

Dr. Sondern: Yes, Governor, it's pneumonia control and Dr. Parran and I believe the time is ripe for a concerted effort to cut down the appalling total of deaths caused by this disease.

Governor Lehman: You told me something of this before, Dr. Parran, when you asked me to increase the appropriation for the State Laboratory so that you could make a new serum for the treatment of pneumonia. Do you mean that you need more money?

Doctor Parran: No, Governor Lehman. We need your interest and your help, but

^{*} In connection with the Utica Academy of Medicine. † Independently arranged.

we are not asking for money this time. The fifty thousand dollars you recommended in your budget message to the Legislature last night will go a long way toward supplying scrum for all pneumonia cases in which serum treatment is of value.

Dr. Sondern: And it will be good serum, too, Governor. The State funds are well spent for that purpose.

Governor Lehman: You imply that not all pneumonia cases can be helped by serum. Why not?

Dr. Sondern: Because there are 32 types of pneumonia germs, and serum has been conclusively proved reliable only for Type I, the most common variety. If used early enough it has been shown that serum will cut the number of these deaths in half, or even by two-thirds. We hope within the year to establish its value for one or two other types.

Dr. Parran: Yes, Governor. It is perfectly accurate to think of pneumonia in these terms. This disease causes a loss of 12,000 lives in New York State each year,—a number equal to the entire population of a good-sized city—Tonawanda, for example; or Beacon, or Fulton, or Oneonta. If each year such a city were to be destroyed by some strange, new plague, we would think no cost too great, and no effort great enough to put an end to such loss of life!

Governor Lehman: And do you gentlemen seriously believe that something can be done about this, now, when these pneumonia deaths have been going on for years?

Dr. Sondern: We do believe it. For one thing, we have seen a comparable campaign bring solid results. You may remember, Governor, how the State Medical Society and the State Department of Health, with the aid of interested citizens, organized the drive against diphtheria ten years ago. Today, diphtheria has almost disappeared in many parts of the State.

Governor Lehman: That's interesting. How many deaths did we have from diphtheria last year, Dr. Parran?

Dr. Parran: About one hundred.

Governor Lehman: How many ten years ago?

Dr. Parran: More than a thousand.

Governor Lehman: That is splendid. Can you repeat the performance for pneumonia?

Dr. Sondern: The prevention of pneumonia deaths on a large scale is a much more difficult task, because we can not as yet immunize against it, before the indi-

vidual becomes ill, as we can against diphtheria.

Governor Lehman: Then how do you expect to get results? The use of serum for the treatment of pneumonia isn't particularly new, is it?

Dr. Sondern: There are two reasons why we feel hopeful now. Recently we have learned how to produce a concentrated scrum which is easier to use and gives better results. Thanks to the foresight of your State Department of Health, Type I serum is freely available to meet all requirements of up-state physicians. Serum is important, but also of importance is the fact that we have developed a quick laboratory test by which we can tell one type of pneumonia germ from another.

Dr. Parran: Any good laboratory now can telephone a report to the doctor attending a pneumonia case half an hour after the sample of sputum has been received. Formerly it took a whole day.

Dr. Sondern: Since much of the value of the scrum depends upon its being administered early, you can see, Governor, that this is a great gain.

Governor Lehman: Yes, I can understand that these things would help. But how are you organized to get this better treatment to the individual patient? What is your plan of action?

Dr. Parran: As in the case of the diphtheria campaign, Governor Lehman, this is a joint effort. The State Department of Health directs the program, supplies the serum, makes sputum examinations for doctors to determine the type of pneumonia, assists in the organization of local nursing services for the care of pneumonia patients, and in the education of citizens to cooperate. The State Association of Public Health Laboratories through its 77 laboratories in 35 counties also helps to carry the load of making quick and accurate examinations. The Commonwealth Fund and the Metropolitan Life Insurance Company have made voluntary contributions to the cost of the campaign. Greatest of all is the contribution of the State Medical Society. Dr. Sondern, won't you tell about that?

Dr. Sondern: The State Medical Society has assumed as its responsibility the post-graduate training of its own members by pneumonia specialists. The most up-to-date scientific information on the treatment of pneumonia has been placed in the hands of the family physician. We believe that pneumonia patients every place in the State will receive the high-type, modern treatment upon which their lives depend. In addition,

the Society is devoting itself wholeheartedly to the task of education, using every possible means to bring home to the families to whom pneumonia may come this winter the necessity of swift, intelligent cooperation with the family doctor in his fight to save pneumonia victims.

Dr. Parran: As we said before, Governor, our need now is not for money, nor serum, nor professional cooperation. It is the need of getting public attention. We can supply the best of medical and nursing care; the best of laboratory service. We can not supply in people the disposition to take their colds seriously; for in the management of colds there is a simple means of preventing many cases of pneumonia—even the types which serum will not help.

Dr. Sondern: Yes, a great many pneumonias start from a neglected cold. I wish I could picture for you from my 30 years' experience the many instances of needless death from this cause. The child who went to school with a feverish cold: came home with wet feet; then a chill, a high feverpneumonia! The working man who was reluctant to lose a day on the job because of a cold—he lost his job forever! The mother who felt she couldn't go to bed for her cold because she had housework to do and children to care for-her children are motherless now! The professional man who felt he must not break appointments except for serious illness-he never kept another appointment! Ignoring danger signals had the same result for all of them; the cold plus neglect equalled pneumonia. And too frequently, in the past, pneumonia has spelled death.

Governor Lehman: What are the chief danger signals?

Dr. Sondern: Pneumonia is an inflammation of the lungs. Cough, fever, chill, pain or heaviness in the side or chest, spitting of blood—all mean danger. Sometimes these first signs are slight and often disregarded. I have seen so many patients who have had pneumonia for several days before it was recognized.

Dr. Parran: The person who feels that way should go to bed at once and call a doctor.

Dr. Sondern: Staying in bed conserves the patient's resistance, so he can ward off the cold himself and prevents him from spreading it to others.

Dr. Parran: More than that, it keeps him out of contact with other persons apparently well, who may be carrying around some vicious pneumonia germs ready to attack just such an easy mark.

Dr. Sondern: Moreover, pneumonia is dangerous in that its poisons, or toxins, place a great strain on the heart. Good nursing care is essential. That, too, may make the difference between life and death.

Dr. Parran: In this connection, Governor, you will be interested to know that for the more than 500 WPA nuhses, working in the State under our supervision, the care of pneumonia cases among the needy will be a first obligation. Visiting nurse associations in upstate cities are offering extra service to pneumonia cases for, as Dr. Sondern points out, it has been shown that many lives can be saved when full nursing care is given to pneumonia.

Governor Lehman: If you could get the majority of people to follow your rules, gentlemen, how many lives do you think could be saved?

Dr. Parran: We have given a good deal of thought to that question, Governor, and believe that one-fourth of the present deaths could be prevented—three thousand lives a year saved—if we could get people to follow this simple rule: If you have a cold, go to bed. If you have a cold with a fever, stay in bed and call the doctor. The doctor, of course, will administer serum when needed and arrange for adequate nursing care.

Governor Lehman: The rule may be simple, but I am fully aware that the problem you describe is exceedingly difficult. It is a human characteristic to believe that no matter what happens to others, we ourselves can escape the results of breaking health rules.

I agree with you, however, that the saving of these lives is worth every effort we can put into it. You hold out to me the hope that three thousand lives can be saved each There is no service the State can render which would mean more in terms of humanity. For I can think of these statistics only in human terms, gentlemen. To me, three thousand lives means homes unbroken; fathers saved for the support of their families; mothers spared for the care of their children; sons and daughters living to fulfill their parents' hopes. I can be dispassionate enough about material problems. None of us may fail to be passionately concerned about human problems. you say, these lives will continue to be wasted by our failing to do what we know how to do to save them, then further inaction would be criminal neglect.

Dr. Sondern, I am glad you feel that the State is doing its share to cut down pneumonia deaths through the work of its laboratory and the services of our health

officers and nurses Will you tell the physicians of New York that we shall work with them to the finish in this campuign to

save life?

Dr Parran, will you express to the organizations and individuals who are so generously cooperating in this great work, my most sincere personal thanks. If after ten years of effort, you have almost conquered diphtheria it is my hope that in 1946 we shall have made comparable progress against the pneumonia scourge Since the professional resources for the fight seem to be well organized, it seems obvious that your whole present problem is that of educationand education on a scale you doctors and health officers have never before undertaken! Surely, everyone will help when he understands the need for help-every physician

and nurse in the State, newspapers, radio stations, schools, churches—all the forces which influence public opinion and move men to action. As an initial step I intend to issue an executive proclumation calling public attention to the task and its tremendous reward. You may expect it tomorrow.

Further than that, if there is anything I can do personally or if other departments of the State government can serve your

purpose, you will find us ready

Gentlemen, I thank you for the story you have brought me tonight. I believe that you will succeed in your endeavor. I believe that through such teamwork of State and cutizen as you describe we shall conquer pneumonia and save these wasted lives.

Committee on Legislation

Bulletin No 3

January 23, 1936

HEARINGS Tuesday, January 28, joint hearing before Judiciary and Codes Committees on all crime bills, including jury

exemption bills; 2 00 P.M.

NEW BILLS INTRODUCLD Senate Int. 348—Twomey, Assembly Int 446—Steingut; amends Chapter 798, Laws of 1931, by extending to February 15, 1937, life of Temporary Emergency Relief Administration Referred to the Finance Committee in the Senate and the Relief and Welfare Committee in the Assembly

Comment Another bill relating to the extension of the TERA for another year

Senate Int 377—Quinn, Assembly Int 411—Bush, adds new section to the Mental Hygiene Law, making it a misdemeanor to bring poor or indigent persons into State for care or treatment at State expense, in institutions within the Mental Hygiene Department Referred to Codes Committee in the Senate and Public Health Committee in the Assembly.

Comment A Department of Hygrene measure intended to prevent what has come to be an abuse of our hospital system Persons residing here have been bringing relatives who are residents of other states to New York State and entering them into our

hospitals.

Senate Int 383—Feld, adds new article to the Public Health Law for regulating practice of electrolysis, which is defined as method used for permanent removal of superfluous hair by means of an electric needle Referred to the Public Health Committee

Comment This bill was before the Legis-

lature last year but it was then referred to the Committee on Education

Senate Int 425—Kirkland, Assembly Int 483—Whitney, amends the Agriculture and Markets Law for testing bovine animals for Bang's disease and mastitis, as well as for tuberculosis, relative to sale of such infected animals, and providing for indemnities Referred to the Committees on Agriculture

Comment A copy of this bill has not as yet been received and will be commented

upon in our next bulletin

Sente Int 442—Nunn, Assembly Int 550—Fitzpitrick, adds new sections 188 to 193, Labor Law, by providing no employee of any hospital shall be required to work more than eight hours a day or 48 hours a week Referred to the Labor Committees

Provides that all hospitals Comment shall be classified in three groups (a) Hospitals conducted for the indigent sick by the State or any political subdivision thereof. (b) Hospitals conducted as charitable or non-profit-making institutions, (c) Hospitals conducted for profit by private corpora-tions or individuals. And further provides that all employees shall serve no more than eight hours in any twenty-four, and "Emploves' shall be deemed to include any person performing any work whatsoever for compensation or wages and/or maintenance and/or partial maintenance in connection with the operation of any hospital, and shall include internes, office employees, watchmen. special policemen, nurses, student nurses, attendants, orderlies, porters, engineers, firemen, custodians, maids, kitchen workers, and each and every person employed in connec tion with the operation of any hospital" Each employee shall be entitled to receive twentyfour consecutive hours of rest in any calendar week. Exceptions: "(1) Laboratory or other employee who customarily works less than eight hours a day, shall not be required to increase the number of his working hours per day; (2) In cases of extraordinary emergency during the prevalence of an epidemic, plague or other catastrophe, the provisions of this title in relation to hours of labor may be modified during such time."

Assembly Int. 412—Bush, amends the Mental Hygiene Law by providing in case of residents of states with which there is no reciprocal agreement, requirements necessary to gain residence in this State shall be not less than those required for acquiring residence in state from which non-resident comes. Referred to the Public Health Committee.

Comment: Another Department of Hygiene measure intended to make similar the laws of our State to other states with which we have reciprocal relationships.

Assembly Int. 511—Lo Re, amends the Education Law by making compulsory transportation and education of physically handicapped children, such children to mean children certified by State or local health boards or medical board of a board of education, as blind, cardiopathic, crippled, deaf, epileptic, tubercular or otherwise so afflicted as to be in need of transportation and instruction. Referred to the Education Committee.

Comment: This provision is already in the law as a permissive arrangement. The amendment would make it mandatory not only on the State Department but also upon local boards of education.

The Committee on Legislation held a conference in the Bureau office on Tuesday, January 21, and reviewed the bills that were before the Legislature at that time. Their action upon the bills follows:

APPROVED: Senate Int. 12—Buckley; Assembly Int. 30—E. F. Moran; Senate Int. 62
—Williamson: Senate Int. 104—Feld; Senate Int. 134—Desmond; Assembly Int. 136—Taylor: Senate Int. 135—Nunan; Assembly Int. 115—Fitzpatrick: Assembly Int. 332—Justice; Senate Int. 177—Kirkland; Assembly Int. 40—Bartholomew; Senate Int. 178—Kirkland; Senate Int. 220—Schwartzwald; Assembly Int. 215—Bush; Assembly Int. 1—Whitney; Assembly Int. 84—Dunn; Assembly Int. 93—McCaffrey; Assembly Int. 204—Otto.

OPPOSED: Assembly Int. 83-Doyle.

No Comment: Senate Int. 57—Wicks; Assembly Int. 61—Wadsworth; Senate Int. 233; Assembly Int. 200—Budget Bill.

A proposed lien bill, submitted by the Committee on Economics, was presented by Dr. Elliott, Chairman. It was considered and referred back to Dr. Elliott's committee

with recommendations that certain modifications and additions be incorporated and resubmitted promptly.

The Legislative Committee also decided to have an amendment to the Pharmacy Law prepared, requiring the distribution of barbituric acid preparations by prescription only.

Another recommendation was that an amendment to the Education Law be drafted which will require that physicians from foreign countries seeking a license to practice in New York State, be required to take the licensing examination unless those countries grant licenses to American physicians to practice there without examination.

The Committee also decided that an amendment should be drafted to the Education Law that would make it a misdemeanor for physicians to advertise for patronage.

The Committee selected Thursday, February 6, as the date for the annual conference of County Society legislative chairmen. The conference will be held at the Hotel Ten Eyck, Albany, beginning about 10:00 A. M. It is hoped that every county chairman will find it possible to arrange his work so that he can be present at this conference. As usual, his travel expenses will be refunded by the Society.

Bulletin No. 4

January 29, 1936

None of the bills in which we are interested has been acted upon since our last bulletin and no further hearings have been announced. The following new bills have been introduced:

Senate Int. 503—Mandelbaum, enacts the Health Insurance Law, as Chapter 23-a, Consolidated Laws, for establishment and administration of system of health insurance, employer to pay into fund amounts ranging from 3½ per cent to 1½ per cent of total wages, based on weekly wage rate, employee to pay from one per cent to three per cent of his wages according to weekly rate, and State to pay 1½ per cent of total wages paid by employers, and appropriating \$100,000. Referred to the Insurance Committee.

Comment: This is the Epstein Health Insurance Bill which we opposed last year. We are informed that no changes have been made in the bill and Senator Mandelbaum has said that he will not attempt to move it immediately. It was handed to him for introduction and his future action will depend largely upon the manner in which it is received. Hence we suggest that you write Senator Samuel Mandelbaum and members of the Senate Insurance Committee, to whom the bill has been referred—your opposition

to the bill. (See Digest of Bill 503—Mandelbaunt.) Senate Committee on Insurance: D. T. O'Brien, Chairman, Thomas F. Burchill, John T. McCall, Stephen J. Wojtkowiak, Lazarus Joseph, Frank B. Hendel, Joseph A. Esquirol, James A. Garrity, Jacob J. Schwartzwald, Jacob H. Livingston, Nelson W. Cheney, Joe R. Hanley, Pliny W. Williamson, Martin W. Deyo, C. Tracey Stagg, William H. Hampton.

Senate Int. 528—Kelly; Assembly Int. 671—Langenbacher, adds new article to the Public Health Law, establishing a division of foods in the Health Department to investigate methods by which foods are prepared, including bakery products, confections, and frozen desserts; to experiment in Laboratories to determine relative calory value of various foods; fix standards for menus for hotels, restaurants, and other eating places, etc.; and appropriating \$50,000. Referred to the Finance Committee in the Senate and the Ways and Means Committee in the Assembly.

Senate Int. 536—Schwartzwald; Assembly Int. 624—Bush; amends the Public Health Law by permitting State Health Commissioner to deputize any assistant, administrative officer or division director to perform in his place any act he is empowered to do. Referred to the Health Comercial State of the State of the State of the Health Comercial State of the Health Comercial State of the S

mittees.

Senate Int. 563—Byrne, Judiciary Law, by providing jury duty exemption only for lawyers, doctors, clergymen, firemen, policemen, U. S. soldiers and sailors, ships' officers, and any member of active militia of State. Referred to the Judiciary Committee.

Comment: Provisions regarding physicians are identical with Senate Int. 12—Buckley; Assembly Int. 30—E. F. Moran. Assembly Int. 623—Breitbart, amends the

Domestic Relations Law by prohibiting a town or city clerk from accepting an application for marriage license unless accompanied by record of standard laboratory blood test. Referred to the Judiciary Committee.

Assembly Int. 625—Ehrlich, adds new section 220-f, Labor Law, limiting hours of labor of employees in State institutions in Mental Hygiene Department to eight hours a day and forty-eight hours a week. Re-

ferred to the Labor Committee.

Assembly Int, 654—Potter, adds new section 220-f, Labor Law, by limiting hours of labor of nurses and other employees in State hospitals to not more than eight hours a day, eight consecutive hours in any twenty-four to constitute a legal day's work. Referred to the Labor Committee.

In our last bulletin we were unable to discuss Senate bill Int. 425—Kirkland: Assembly Int. 483—Whitney, because we had not seen a copy of it. We are now in a position to say that the bill is almost identical with the other Bang's disease bills. It is less desirable in that it considers mastitis as

infectious as Bang's disease.

While as yet there has not been a great deal of legislation introduced in which we are interested, there are, nevertheless, very important matters that we should discuss at the conference to be held on Thursday, February 6th, and we hope that every chairman will find it possible to be present: or, if it is going to be impossible for him to come, that he will send as a substitute a member of his Committee.

Digest of Bill 503 (Mandelbaum)

PREMIUMS-ARTICLE II

Premiums; Allotted by Board and paid to State Commissioner of Taxation.

Employer: 3½% on \$20 per week or less, 2½% on \$21 to \$40 per week, 1½% on \$41 plus.

Employees: 1% on \$20 or less, 2% on \$21 to \$40, 3% on \$41 plus.

State: 11/2% of total of all wages paid periodically.

Tax exempt.

CASH BENEFITS-ARTICLE III

Cash benefits begin six months after October 1, 1935.

Qualifications: 1. Loss due to disability. 2. Served notice of disability. 3. Had no less than 104 days' employment or cash voluntary insurance within the preceding

twelve months or 160 days in preceding twenty-four months.

Disqualification: Eligible for benefit under the workmen's compensation.

Waiting period: Disability amounting to five days' full time daily wages.

Amount of Cash Benefits: 50 per cent of wages not to exceed \$15 per week. With dependent spouse 10 per cent or \$3 per week additional. With dependent one child 5 per cent or \$1.50 per week additional. With dependent two children 15 per cent or \$4 per week additional.

Duration: Total of 156 days in any fiftytwo weeks. No benefits until a lapse of sixty days after termination of previous period.

Qualifications extended after employment ceases: One day for every five of previous employment.

MATERNITY BENEFITS-ARTICLE IV

Regular Benefit: From six weeks before to six weeks after birth of child.

Qualifications: 1. Has had 250 days of employment during preceding twenty-four months. 2. Has registered. 3. Is receiving prenatal care.

Disqualification: If gainfully employed benefit shall not be paid.

Exempt Period: Maternity benefit shall be paid although period of eligibility under section 25, article 3 may have expired.

Added Benefit: If prenatal care as prescribed \$15 additional to, 1. Employee qualified to receive regular benefits. 2. Wife of an employee qualified to receive benefits. 3. Widow of employee who at his death was so qualified if child is born within ten months.

Prolongation of qualifications: If employment ceases, eligible for one day additional for every five days of previous employment.

MEDICAL BENEFITS—ARTICLE V

Eligibility: Employee, dependent spouse, dependent children and such other dependent members living in same household.

Qualifications: 1. Has had not less than ten days employment in preceding three months. 2. Has given notice for same.

Disqualifications: If entitled to benefit under Workmen's Compensation.

Extent of Benefits: 1. Physician at office, home or hospital or elsewhere in prevention,

diagnostic or therapeutic, periodic examination and immunization. 2. Hospital treatment and care including nursing. 3. Prenatal care in home or hospital. 4. Special services of surgeon, diagnostician, etc. 5. Services of laboratories and clinics. 6. Services of dentist for exodontia, plastic fillings, prophylactic care. 7. Services of dentist for correction of potential disabling conditions.

Duration of Regular Medical Benefits: 1. General medical or dental care for twenty-six weeks, specialist or laboratory twelve weeks. 2. If employment ceases general services twenty-six weeks more and twelve weeks of specialism or laboratory. 3. Hospitalization for 111 days (21 without charge and 90 at from 10 per cent to 25 per cent cost). 4. General care for no more than ninety days in any consecutive 104 weeks to persons sixty-five.

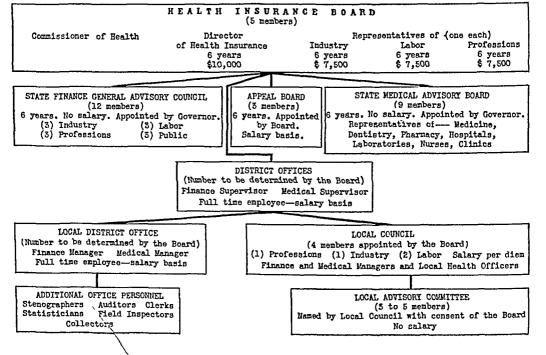

Additional Medical Benefits: 1. Drugs, medicines, and ordinary appliances or prescriptions. 2. On prescription, nursing service. 3. Institutional care for convalescents. 4. On prescription, special appliances. 5. Special dental care.

Discretion of Board: 1. May provide any or part of additional benefits for entire State or localities. 2. Provide additional benefits free or for part of cost.

Development of Facilities: 1. Construct hospitals, laboratories, clinics, etc.

VOLUNTARY INSURANCE—ARTICLE VI Eligibility: Resident of State employed

SET-UP OF MANDELBAUM BILL (503)

not subject to this chapter under sixty-five years and earning less than \$60 per week.

Premium 11/8 per cent of wages.

Voluntary Medical Benefits: Others and their dependents than those stipulated in other parts of chapter if they pass a physical examination, 1. Resident of State, not disabled, income \$60 per week or less and not sixty-five years. Premium 33% per cent of income. 2. Resident of State, not disabled, had not less than 260 days of employment or voluntary insurance in preceding three years and income does not exceed \$100 a week. Premium 33% per cent of income. 3. Resident of State who within preceding three years had 260 days employment and/or voluntary medical insurance, unemployed though capable of employment. Premium 338 per cent of what Board considers fairly represents weekly income. 4. Any resident receiving old age or unemployment insurance from any government officer provided he pays into fund.

Voluntary Additional Medical Benefits: 1. For additional voluntary premium any of additional medical benefits. 2. Either to entire State or section or groups as board may wish. 3. Premium shall be fixed to bear complete cost of special service. 4. All rules and regulations may be modified at

any time.

State's premium 1/3 of all sums paid in.

ARTICLE VII

Section 65. Duties and Powers of the Board: 1. Make rules and regulations for administration. 2. Employ district and local finance and medical supervisors and managers, and other employees and assistants; determine their salaries and other duties. 3. Furnish and pay benefits. Supervise all acts of district finance and medical managers and local councils, 5. May disregard or nullify any acts of local councils. 6. After hearing remove any physician or dentist, etc., from the list. 7. Provide for non-residents who are entitled. 8. Make inquiries into causes of sickness and injuries. 9. Promote health and safety; take steps to prevent sickness. 10. Cooperate with the Health Officer. 11. Make contributions or donations to hospitals or laboratories.

Section 69. Function of District Offices. Finance Supervisor: 1. Supervise and direct collection of premiums. 2. Disbursement of cash and maternity benefits. 3. Providing and defraying cost of medical benefits. Medical Supervisor: 1. Supervise and direct administration and furnishing of the cash,

maternity and medical benefits.

Section 73. Duties of Local Councils: 1. Supervise collection of premiums. Supervise payment of cash and maternity benefits, notices of injury and disability and expenses of disbursements for medical care. 3. Supervise furnishing of medical benefits. 4. Cooperate with public health agencies. 5. Prepare and publish lists of physicians and dentists. 6. When necessary, secure assistance of another district. 7. Arrange for remunerating physicians, dentists, etc.
(a) Salary. (b) Per Capita. (c) Fee system based on character of service. (d) Any combination. (Majority of physicians or dentists engaged must agree to method.) 8. After hearing remove physician et al from list. 9. Distribute patients. 10. Submit reports.

Section 75. Duties of Local Finance Manager: (Full Time). 1. Manage collection of premiums. 2. Manage payment of cash or maternity benefits. 3. Manage disbursements of medical benefits. 4. Manage all other matters. Duties of Local Medical Managers: (Full Time). 1, Pass upon notices of sickness, injury or disability. 2. Pass upon claims for eash, maternity and medical benefits. 3. Pass upon furnishing medical benefits. 4. Pass upon claims by persons furnishing medical benefits. 5. Pass upon complaints with respect to medical benefits. 6. Pass upon services rendered by all furnishing medical benefits.

MEDICAL RADIO BROADCASTS

The Medical Information Bureau of the New York Academy of Medicine announces the following broadcasts from Station WABC and the Columbia Broadcasting System network:

Thursday, February 20, 1:45 P.M.— Speaker: Dr. B. S. Oppenheimer, Assistant Professor of Clinical Medicine, College of Physicians and Surgeons, Columbia Univer-

sity. Subject: "Imaginary Heart Disease."
Thursday, February 20, 1:45 P.M.—
Speaker: Dr. G. Randolop Manning, Clinical Professor of Gastro-Enterology, Polyclinic Medical School and Hospital. Subject: "From Caveman to Dyspepsia-A Survey of Modern Life."

Thursday, February 27, 1:45 P.M.— Speaker: Dr. Thomas T. Mackie, Physician to Out-Patients, New York Hospital. Sub-ject: "The A, B, C-Aids to Nutrition-Vitamins."

An operation on a cat to remove a twoshilling piece it had swallowed moves the London Punch to observe that it isn't often you find so much in the kitty.

Public Health News

As previously announced in *Health News*, the special program for the control of pneumonia was inaugurated on January 1. This program is unique in that it is a cooperative undertaking actively participated in by several agencies, including the New York State Medical Society, State Association of Public Health Laboratories, Commonwealth Fund, Metropolitan Life Insurance Company, and the State Department of Health.

The immediate objectives of the program are as follows: production and distribution without cost to physicians of a highly concentrated and purified type I antipneumococcus serum; extension of approved laboratory service for sputum typing; emphasis to physicians of the importance of the early diagnosis of pneumonia based upon both symptomatology and laboratory findings, and of the advantages of serum therapy for type I cases; instruction of the general public as to the importance of early and adequate medical care for severe acute respiratory infections; and provision of facilities for adequate bedside nursing care in so far as possible.

The Division of Laboratories and Research, on December 30, forwarded an initial supply of concentrated type I antipneumococcus serum to seventy of the supply stations throughout the State. Distribution of the amount prepared—sufficient to meet over twice the demand for unconcentrated serum during the first three months of last year—will be continued. The serum is put up in vials containing 20 cc. (equivalent of 25,000 units) and will be distributed without charge to physicians through state laboratory supply stations. The estimated average total dose is 100,000 units. A less amount is frequently ample for cases treated early. All physicians obtaining serum will be requested to fill out a short report at the

end of the patient's illness. Physicians are also asked to take only as much serum as is necessary for the adequate treatment of each individual case and to return promptly any unused material, since the serum is very expensive and the supply limited.

Facilities for sputum typing by the rapid (Neufeld) method are now available in seventy-seven approved laboratories throughout the State. Plans are under way for extending the service and it is hoped that eventually typing facilities will be within reasonable access of physicians in all parts of the State except the most sparsely settled

regions.

Adequate nursing care is a recognized necessity in the treatment of pneumonia. Official and voluntary nursing organizations such as the New York State Nurses' Association, various visiting nurse associations, the Metropolitan Life Insurance Company, and the Division of Public Health Nursing are considering ways and means for providing bedside care and supervision. Welfare officials are to be requested to make special effort to see that adequate nursing care is provided for pneumonia patients otherwise unable to pay for such care.

unable to pay for such care.

The New York State Medical Society through its Subcommittee on Public Health and Education is prepared to make suggestions and to provide speakers for meetings, and conferences on pneumonia attended by medical groups. Many county medical societies have already held, or are planning to hold, special meetings devoted to the various aspects of pneumonia, and a keen interest in the program has been manifested by physicians and health officials. It is hoped that similar interest in reducing mortality from pneumonia may be created in the minds of the general public throughout the State.—

Health News, January 20, 1936.

Pneumonia

Leaflet Issued by The State Department of Health

Antipneumococcus serum, type I, is prepared, tested, and distributed by the Division of Laboratories and Research. The serum is concentrated and purified.

Under no circumstances are any of the antitoxins, sera, vaccines, or other preparations distributed by this department to be sold. A violation of the above rule will subject the violator to the penalty prescribed by Section 1740 of the Penal Code.

Striking results in serum therapy have followed early treatment of many type-I

cases with type-I antipneumococcus serum. When given under such conditions the mortality has been markedly lowered.

The serum in bottles containing 20 c. c. (equivalent of 25,000 units) is distributed, upon special request, through the district supply stations for the treatment of suitable cases in which the presence of pneumococcus, type I, is indicated. In emergencies it may be obtained directly from the State Laboratory in Albany, or from the Branch Laboratory, 339 East 25th Street, New York City.

In each package is included a small bottle containing normal horse serum diluted 1:10 with salt solution for use in the tests of sensitivity to horse serum.

Sterile physiological salt solution in 10 c.c. amounts for use in preparing the dilution for the intracutaneous test of susceptibility, for rinsing water from syringes and needles which have been boiled, and for diluting the serum for the preliminary injection may also be obtained from supply stations, when not otherwise available.

Every physician using antipneumococcus serum provided by the State is asked to report the results of its use on the form supplied with each package. The form should be filled out completely and returned to the Division of Laboratories and Research, New Scotland Avenue, Albany. A record of the therapeutic action is essential for the maintenance of high standards of potency.

DIAGNOSIS

A specimen of sputum should be sent with the least possible delay to the nearest laboratory approved for pneumococcus-type differentiation. In the case of children and occasionally of adults, it may be necessary to collect the sputum from the throat with a sterile swab during the act of coughing. When type-I pneumococci are indicated, type-I antipneumococcus serum should be given immediately. Prompt diagnosis and early administration of serum are essential.

The directions for the collection of sputum for laboratory examination are given in the circular accompanying the outfits in which the material may be submitted, or can be learned through consultation with the director of the laboratory making the examination.

DIRECTIONS FOR THE USE OF ANTIPNEUMOCOCCUS SERUM

Dosage. To be effective the serum must be given intravenously. The first dose should be 40 c.c. (equivalent of 50,000 units). It is divided into a preliminary injection of 1 c.c. followed in from one-half to one hour by 39 c.c. A second dose of 40 c.c. is usually given from four to six hours after the first. When practicable, dilution of the serum before administration is desirable. Further administration depends upon the results of treatment and the condition of the patient. In cases of over 72 hours' duration and in those failing to show improvement within 12 hours, more than 80 c.c. (100,000 units) of serum may be required.

Precautions Against Anaphylactic Reactions. The injection of horse serum, whether concentrated or unconcentrated, may, in rare instances, incite severe or even fatal reactions of an anaphylactic character in highly susceptible persons. They usually occur in persons who suffer from hav fever, asthmatic or other allergic symptoms, or who have previously received an injection containing horse serum. Hence, the previous history should always be obtained. It is, therefore, highly important to determine in all instances whether a condition of hypersusceptibility exists. For this purpose an intracutaneous test and an ophthalmic test are generally used. Intravenous injection of serum may induce severe or fatal reactions in persons who fail to react to the tests. Absence of systemic reactions when skin sensitivity has been demonstrated has also occurred.

Intraculaneous Test. An area on the inner surface of the forearm is gently cleansed with soap and water, then alcohol without reddening. From the 1:10 dilution of normal horse serum contained in each package of antipneumoocous serum, prepare a 1:100 dilution in sterile physiological salt solution and inject 1 cc, intracutaneously. If a wheal, with or without erythema, does not appear at the site of injection within from 10 to 15 minutes, the injection of serum is usually a safe procedure. If the skin reaction is positive, serum administration is generally contraindicated unless every facility is at hand to treat a possible severe reaction.

Ophthalmic Test. Drop into the conjunctival sac one drop of the 1:10 dilution of normal horse serum supplied in each package. If definite congestion of the conjunctiva develops within 10 minutes with a sensation of itching and burning of the eye, a dangerous sensitiveness to horse serum is indicated and intravenous injection is contraindicated unless desensitization is practicable. Should the local reaction be marked, it may readily be controlled by prompt application of epinephrine (1:1000) to the eye.

"Descusitization." The procedure of "desensitization" and the therapeutic administration of serum are not advised in the case of patients with a positive skin or ophthalmic test except under conditions such as may be found in a well-equipped hospital. Serum therapy even under these conditions must be considered hazardous. The following procedure has been used in attempted desensitization. Subcutaneous injections of the serum, beginning with .01 or even less, are given at one-half-hour intervals until 1 c.c. is reached by doubling or tripling the dose if no reaction develops. If 1 c.c. injected subcutaneously incites no reactions, 1 c.c. may be given intravenously one-half hour later. Should this give rise to no reaction, the doses may be increased very gradually until the desired amount has been administered. With a few individuals the limit of tolerance will soon be reached. When an interval of more than three days elapses between injections of serum, the danger of serious reaction is considerable and fatal results even after attempted desensitization have been reported.

Administration of Serum. Intravenous injections are made into the median basilic vein very slowly by gravity, or directly at a

rate of 1 c.c. per minute or even more slowly than this at first. The physician should be on the alert for symptoms suggesting Since the serum protein is anaphylaxis. precipitated by water, needles and syringes after boiling should be rinsed with sterile physiological salt solution or, if facilities are available, sterilized by dry heat. The serum for the preliminary injection of 1 c.c. should be diluted immediately before administration with from 5 to 10 c.c. of warm, fresh, sterile physiological salt solution. When practicable, subsequent doses should be diluted with an equal volume of salt solution. If any sediment is present, the serum should be removed carefully from the bottle so that it is not carried over. Special care should be taken that the serum is at body temperature when injected.

Serum Reactions. Anaphylactic reactions are extremely rare. They usually appear within the first few minutes following serum administration, but they may occur as late as one hour after treatment and also after the second or third dose. The symptoms may include dyspnea, cyanosis, urticaria, lumbar or abdominal pain, and collapse. Hypodermic injection of, from .6 c.c. to 1.0 c.c. (10 to 16 minims' of epinephrine

solution (1:1000) will usually give prompt relief. Therefore, a fresh solution in a hypodermic syringe should be kept at hand, since time may be an important factor. Moderate or severe reactions characterized by chill, rise in temperature, or rapid pulse occasionally occur. They are evanescent, however, and rarely require more than symptomatic treatment. Serum rashes sometimes develop after five days. They may or may not be accompanied by other symptoms While conoccurring in serum disease. siderable temporary annoyance may be caused, they should not be regarded as serious or as having any lasting effect. Physicians are advised to remain with the patient for at least a half-hour after administration of the serum so that they will be readily available in case a severe reaction develops.

Physicians are again cautioned against resuming the treatment after an interval, without repeating the sensitivity tests. Surgical asepsis is essential in the administration of the serum. The period of convalescence should not be shortened in eases recovering promptly under serum treatment, quite the contrary.

VICTIMIZING THE DEAF

The improvement in hearing aids has had in England to the victimization of sufferers by unscrupulous firms who make extravagant claims. Perfect hearing is promised, irrespective of the causation and degree of deafness or the age of the sufferer.

The National Institute for the Deaf is doing valuable work in protecting the public against fraud. It has issued for the information of the deaf a booklet entitled "The Choice of Hearing Aids." The deaf are advised in the first instance to take medical advice as to whether an aid is likely to be beneficial. They are warned of the dangers of exploitation and advised not to sign any contract with a hearing aid purveyor without reading it carefully.

The institute maintains a list of firms on which the deaf can rely for guidance and fair dealing. These firms have agreed to allow an extended trial at home of any instrument subject to payment of five per cent of its value. Thus the deaf can avoid being gulled by misleading advertisements and circulars of firms who refuse this home trial and who decline to make any financial adjustment if the aid sold proves unsatisfactory. As told in a London letter to the AMA Journal, the purchaser of an aid to

hearing is advised to choose a firm whose advertised claims are set forth in moderate terms, to take with him a friend whose voice he knows and who knows his degree of deafness, so that he can make comparison with the vendor's voice, and to insist on a trial of the apparatus at home for a sufficient period, say from two to four weeks. If the instrument does not give satisfaction during this period, it is never likely to do so.

It is pointed out that a carbon microphone can be made more than usually sensitive for a short time by shaking up the granules and adjusting the diaphragm. The granules should therefore be allowed to settle down again before the normal performance of the hearing aid can be assessed. The expense of maintenance, it is pointed out, is greatest for the valve amplifying type, next for the bone conduction type, with its relatively high current consumption, and lowest for the simple telephone type.

Vacillating and dawdling doctors are compared by a recent medical speaker to the chameleon which "nearly busted" trying to change colors to match as he walked across a Scotchman's plaid.

Medical News

Cattaraugus County

A GOOD NUMBER Of doctors "skidded over the various roads to Ellicottville" on Jan. 21 to attend the meeting of the Cattaraugus County Medical Society. Valuable talks on pneumonia were given by Dr. Thomas P. Farmer of Syracuse. Clayton W. Greene, M.D., Professor of Medicine, University of Buffalo; E. S. Rogers, M.D., New York State Department of Health, and E. K. Kline, Dr. P. II., Director of the Cattaraugus County Laboratory.

Dr. S. J. Castilone was elected president of the Medical Staff of the Higgins Memorial Hospital of Olean at the annual meeting. Other officers elected were: Dr. Francis P. Keefe, vice-president, and Dr. Norman

P. Johnson, secretary and treasurer.

Cayuga County

Oppicers of the Cayuga County Medical Society for 1936 are as follows: Dr. George C. Sincerbeaux, of Auburn, president; Dr. Charles T. Yarington, Moravia, vice president; Dr. Cyrus H. Maxwell, Auburn, secretary; Dr. W. A. Tucker, Auburn, treasurer; Dr. M. L. Seccomb, retiring president, Dr. A. K. Bates, Dr. Raymond F. Johnson, Dr. Louis F. O'Neill, Dr. G. Perry Ross, members of the Board of Censors; Dr. C. F. McCarthy, historian.

The Society has started to make a complete history of the society from its founding in 1806 to the present time through the efforts of the society historian, Doctor McCarthy, and other members of the profes-

sion.

A feature of the annual meeting was an exhibition of documents and papers pertaining to the society from the beginning when the major portion of the county was practically a wilderness.

Delaware County

THE 127TH ANNUAL MEETING of the Delaware County Medical Society was held in Delhi on Dec. 18 with fourteen members present. Officers elected were: President, Dr. Orin Q. Flint, Jr.; vice-pres., Dr. Gordon B. Maurer; secretary and treasurer, Dr. William M. Thomson.

The President appointed the following censors: Dr. Charles L. Wakeman, Dr. William M. Thomson, Dr. Thomas L. Craig, Dr. Robert Brittain was elected delegate to the state convention, with Dr. Orin Q. Flint

as alternate.

Dutchess County

MALPRACTICE INSURANCE was discussed at a special meeting of the Dutchess County Medical Society on Dec. 20 by Dr. Frederick E. Sondern, president of the Medical Society of the State of New York, and Dr. Charles Gordon Heyd, chairman of the insurance committee.

Kings County

THE CONEY ISLAND MEDICAL Society has elected the following officers: Dr. Philip I. Nash, president; Dr. Harry J. Diamond, vice president and Dr. Moses A. Bluestone, secretary-treasurer. Through the efforts of the society blood pressure booths which flourished at the resort last summer were found to be illegal and done away with.

DR. SAMUEL SIEGLER has been installed as president of the East New York Medical Society for 1936. The other principal officers are: Dr. Jacob Gutman, first vice-president; Dr. A. H. Marel, second vice-president; Dr. William Levine, treasurer; Dr. Maxwell Katz, assistant treasurer; Dr. Charles Windwer, recording secretary; Dr. Mortimer Kopp, corresponding secretary, and Dr. William Leavitt, historian.

THE CONEY ISLAND HOSPITAL announces vacancies for two assistant physicians for ambulance duty at \$900 with maintenance.

Monroe County

AT THE ANNUAL election of officers of the Monroe County Medical Society on Dec. 17 Dr. Edward T. Wentworth was elected president, Dr. Edward G. Whipple, vice president, and Dr. John J. Rooney and Dr. William A. MacVay were re-elected treasurer and secretary respectively.

Delegates to the state society will be Doctors Warren Wooden, William H. Veeder and W. A. MacVay with Doctors Thurlow T. Huntington, Willis J. Bowen and John J. Rooney as alternates. New members of the Mills Commission are Dr. Arthur M. Johnson and Dr. Albert D.

Kaiser.

Members of the governing board in addition to officers will include Doctor Veeder, retiring president, and Doctors Floyd S. Winslow, Benjamin J. Slater, Warren Wooden, James M. Flynn and Joseph P. Henry.

ESTABLISHMENT OF A Rochester Academy of Medicine Museum as a permanent unit of the Rochester Museum of Arts and Sciences has been announced. The museum, outgrowth of a need long felt by members of

Counsel, Medical Society of the State of New York

Malpractice Action Barred by Release

With the continual increase of automobile accidents, and the proportionally great amount of care rendered by physicians to persons so injured, the outcome of damage suits brought by such persons is always a matter of interest to physicians. Treatment rendered to such persons has sometimes led to malpractice suits. Not until very recently, however, has the effect of a settlement between a patient and the person responsible for the original injuries upon such malpractice suits, been definitely established. The New York Court of Appeals has squarely passed upon that question in a case recently decided by it.*

On November 20, 1931, a small child

was struck and run down by an automobile owned by one G. and operated by one F. The child was taken to a nearby hospital for treatment for her injuries, and her care came under the charge of M, one of the surgeons on the staff of that institution. The patient had a stormy course during her confinement, and remained in the hospital

for several months, and during that time she underwent certain operations. On May 22, 1932, her condition had improved sufficiently that she was on that day discharged

from the hospital and from the care of Dr. M.

Two days later the child's father had himself appointed guardian ad litem of the child, and during June 1932 he brought an action on behalf of the child in the Supreme Court to recover damages for the injuries sustained against F. and G. The father also brought a separate action against F. and G. for the loss of the infant's services and for the expenses he had incurred for her care and treatment. After that action had been started negotiations were entered into between the parties to that action which resulted in August of that year in the settlement of the two actions. The settlement of the infant's action of course was made pursuant to an order of a Justice of the Supreme Court approving the settlement. At the time the order was so made the papers before the Court set forth the condition of the child at that time, and made reference to the care and treatment that the child had received. Thereupon the infant's action was settled by payment of somewhat

* Milks v. M., 147 Misc. 297, 264 N. Y. 267.

over \$3,000 to the guardian and the father's individual action was compromised by the payment to him of \$4,500. The father, pursuant to the Court's order as guardian ad litem executed a general release to F. and G. and also executed a similar release to them in his personal action.

In December of the same year, after the settlement with F. and G. had been completed, the guardian brought another action in the Supreme Court on behalf of the child, and on his own behalf as an individual, this time naming the doctor M. and the hospital as defendants. The complaint was that due to the alleged malpractice of M. and the alleged negligence of the hospital through its nurses and doctors, the plaintiffs were entitled to recover \$100,000 as damages. It was claimed that such negligence and malpractice prolonged and aggravated the original injuries, and also

caused other injuries.

An application was made to the Court at Special Term, setting forth the foregoing facts, for a dismissal of the complaint as to the doctor on the grounds that the release of F. and G. released any rights of action against the doctor. The Court, (Mr. Justice Heffernan, now a member of the Appellate Division for the Third Judicial Department), granted the motion in favor of the doctor, and handed down a well written opinion, which said in part:

Where one who has suffered personal injury by reason of the negligence of another exercised reasonable care in securing the services of a competent physician or surgeon and his injuries are thereafter aggravated or increased by the negligence, mistake or lack of skill of such physician or surgeon, the law regards the negligence of the wrongdoer in causing the original injury as the proximate cause of the damages flowing from the subsequent, negligent or unskilled treatment thereof, and holds him liable therefor. * * *

Conceding malpractice on the part of the defendant M. as charged in the complaint it seems to me that the plaintiffs are precluded from a recovery against him. F. and G. were liable not only for the injuries sustained by plaintiffs but also for the malpractice of the attending surgeon and for the expenses of medical attendance. Having that liability in view they settled with plaintiffs, paying them a substantial sum for a release from further liability. At the time the release was given the child had left the hospital and had already suffered from

Medical News

Cattaraugus County

A good number of doctors "skidded over the various roads to Lilicottville" on Ian 21 to attend the meeting of the Cattaraugus County Medical Society Valurable talks on pneumonia were given by Dr. Thomas P. Tariner of Spracise Clyton W. Greene, M.D., Professor of Medicine University of Buffalo, E. S. Rogers M.D., New York State Department of Health, and E. K. Kline, Dr. P. H., Director of the Cattaraugus County Laboratory

Dr S J Castilone was elected president of the Medical Staff of the Higgins Memorial Hospital of Olean at the annual meeting Other officers elected were Dr Francis P Keefe, vice president, and Dr Norman P Johnson, secretary and treasurer

Cayuga County

Officers of the Cayuga County Medical Society for 1936 are as follows Dr George C Sincerbeaux, of Auburn, president Dr Charles F Yarington Morava vice president, Dr Cyrus H Maxwell, Auburn, secretary, Dr W A Tucker Auburn treasurer, Dr M L Seccomb, returning president, Dr A K Bates, Dr Raymond F Johnson Dr Louis F O Neill, Dr G Perry Ross members of the Board of Censors Dr C F McCarthy, Instoran

The Society has started to make a complete history of the society from its founding in 1806 to the present time through the efforts of the society historian Doctor Mc Carthy, and other members of the profes-

ESTABLISHMENT OF A Rochester Academy of Medicine Muscum as a permanent unit of the Rochester Museum of Arts and Sciences has been announced The museum, output of a need long felt by

the academy for a place where interesting and valuable source material in the fields of medical history and art might be collected, classified, exhibited and studied, has been set up through an agreement between trustees of the academy and the board of commissioners of the municipal museum.

The museum will be operated as an active teaching museum accessible to all citizens of the community who have a legitimate interest in the historical, art or scientific aspects of medicine.

While an effort will be made to build up permanent exhibits, it is planned to have special and rotating exhibitions on subjects which may be timely to physicians and stu-

dents of public health.

Issuing an appeal for donations to the museum of old medical books and paraphernalia such as infant feeding bottles, curious medical bottles, instrument of varikinds, family medicine books amulets to ward off disease, the academy asks that donations be sent to the museum at Edgerton Park or to the Academy of Medicine, No. 13 Prince Street.

New York County

THE NEWLY ANNOUNCED discovery of a nasal spray to prevent infantile paralysis opens an entire new field for experimentation in control of the dread disease, Dr. Park said on Dec. 27. Dr. Park has been experimenting for three years with paralysis vaccine. He said:

"I am still hopeful, but no longer confident, about the ultimate success of any vac-

cine to prevent paralysis.

"Perhaps this spray method of immunization is the simplest solution we have all been

seeking."

Infantile paralysis, Dr. Park said, is almost wholly a disease of the nervous system. He has become convinced that the germ

does not get into the blood at all.

The serum method of treatment has failed completely in cases where the disease was contracted, according to Dr. Park, because the serum reaches only the blood and not the nervous system. For this reason, he is "discouraged" as he contemplates the possibility of ultimately vaccinating successfully to prevent the disease. He said:

"We do know definitely that the germ of infantile paralysis is contracted through the nose and affects the central nervous system. We seem unable to reach the nervous system, but if we are able to change the composition of the mucus to resist the paralysis virus, perhaps we shall have a real pre-

ventive."

The spray, a solution of either sodium alum or tannic acid, was developed by doctors at the Rockefeller Institute, who announced the results of their work at the convention of the Society of American Bacteriologists.

The immunity provided by the present spray is apparently short-lived, it was admitted. From tests on monkeys the doctors' ascertained that, although they seemed to be immune immediately after being treated, in one or two months they were again susceptible.

DR. WILLIAM HALLOCK PARK, noted bacteriologist and hygienist, retired on his seventy-second birthday anniversary, Dec. 30, from active work as director of the New York City Bureau of Laboratories of the

Department of Health.

Dr. Park, under an arrangement worked out by Mayor La Guardia with his acquiescence, will take a six months' vacation, after which he will retire permanently from the directorship and become director emeritus of the bureau. He has held the post fortyone years.

It is expected that at the end of the vacation, the new William H. Park Research Laboratories, named in his honor, will have been completed, so that they can be dedicated while Dr. Park is still nominally in the city's service. He expects to continue working at the laboratories in an advisory capacity.

Dr. Ralph Muckenfuss, acting associate director, will be in charge during Dr. Park's vacation. Dr. Park needed a rest because he has been overworking of late, his associ-

ates said.

Oneida County

THE NEW OFFICERS of the Oneida County Medical Society are: President, Dr. Dan Mellen, of Rome; vice-pres., Dr. William Hale, Jr., of Utica; secretary, Dr. James Irving Farrell; treasurer, Dr. H. D. Mac-Farland; librarian, Dr. T. Wood Clarke; board of censors, Drs. M. D. Graham, W. B. Roemer, F. J. Rossi, H. N. Squier, all of Utica, and Dr. R. B. Gregory, Rome, Dr. Higa. Utica, and Dr. P. P. Gregory, Rome. Dr. Andrew Sloan and Dr. William Hale, Jr., were named delegates to the House of Delegates. The third delegate, who holds over, is Dr. E. M. Griffith, Chadwicks.

The alternate named was Dr. John F.

Kelley.

Dr. G. M. Fisher, whose place Doctor Hale took as delegate, resigned after thirty years' service in that position, during part of which time he served as state president.

Doctor MacFarland, treasurer, reported the largest balance the society ever has had.

Onondaga County

A MAN WHO attended the annual election of officers of Syracuse Academy of Medicine in 1900 as a newspaper reporter was elected president of the organization on Dec. 17. He is Dr. Edwin H. Shepard, consulting physician of General Hospital of Syracuse. Other officers elected were: vice president, Dr. Mortimer G. Brown; secretary, Dr. Leon E. Sutton, and treasurer, Dr. Foster C. Rulison.

FEDERAL FUNDS have recently been made available for the erection of a new building for the University of Syracuse School of Medicine. The new building will be a new unit in a medical center that now contains the City Hospital, Syracuse Memorial Hospital, and the Syracuse Psychopathic Hospital. It will be three stories high and will cost \$1,250,909, according to the Syracuse Herald. It is expected that the building will be completed within a year.

Oswego County

Dr. Ross F. Wolever, of Fulton, was re-elected president of the Oswego County

Medical society on Dec. 17.

Other officers elected were: Dr. Olin J. Mowry, Minetto, vice president; Dr. J. J. Brennan, Oswego, secretary; Dr. J. B. Ringland, Oswego, treasurer; Dr. William McD. Halsey, Oswego, censor.

Dr. Harwood Hollis of Lacona was elected delegate to the New York State Medical society and Dr. Mowry was selected

as alternate.

Queens County

The Medical Society of the County of Queens heard Dr. Morris Fishbein, Editor of the A.M.A. Journal, speak on "Medicine in a Changing World" at its meeting on January 28. Dr. Frederick E. Elliott, Chairman of the State Economics Committee, and Dr. Vincent Juster, Chairman of the County Economics Committee, discussed medical economics, and Dr. James M. Dobbins delivered his inaugural address as president of the society.

Rockland County

Officers of the Rockland County Medical Society for 1936 are as follows: President, Dr. Alexander N. Selman, of Spring Valley; vice president, Dr. George W. Unsworth of Suffern; secretary, Dr. William J. Ryan, of Pomona; treasurer, Dr. Dean Miltimore, of Nyack; censors, Dr. Charles D. Kline of Nyack, Dr. Royal F. Sengstacken of Suffern, Dr. George A. Leitner of Piermont, Dr. Matthew J. Sullivan of Haverstraw and Dr. Stephen R. Monteith of Nyack; Dr. George A. Leitner, delegate to State society, and Dr. Stephen R. Monteith, of Nyack, alternate.

Ulster County

Dr. Edwin C. Fassett of Kingston was elected president of the Ulster County Medical Society, and Dr. Fred Voss of Kingston vice president, on Dec. 17 at a meeting and supper at the Goyernor Clinton Hotel in Kingston. The Medical Society had as guests the Ulster County Bar Association, and the principal speaker was Dr. Harrison S. Martland, professor of forensic medicine at New York University. He took as his subject the medical detection of crime, comparing the medical examiner system with the older coronal method of investigating such cases.

Warren County

THE WARREN COUNTY Medical Society, through the chairman of its legislative committee, Dr. E. B. Probasco, of Glens Falls, has sent a letter to Congressman W. D. Thomas urging a stronger neutrality law. It

says in part:

"Let the Congress enact a law making it a penal offense to manufacture for or ship, directly or indirectly, to any foreign country, then at war, any munitions of war or raw materials capable of being fabricated into such munitions.

"Let responsibility for violation of this law rest on executive officers or managing directors of corporations, members of firms, partnerships, companies or individuals; and let such violations be punished by imprisonment for a term of years and accompanied by a heavy fine."

Westchester County

STARTING A NEW policy, the Scientific Committee of the Medical Society of the County of Westchester is planning a two or three year comprehensive series of lectures or papers, covering all the major fields and problems of medical and surgical science. Each of the papers will be presented by a prominent teacher or practicing exponent in his subject, and each will be, as far as possible, essentially a practical review of the latest proven and accepted advances in diagnosis and treatment in the particular field The entire series, it is hoped, may constitute a useful, integrated post-graduate course of everyday practical value to the active prac-titioner. The first paper was presented on Jan. 21 at a meeting of the society at Bloomingdale Hospital, White Plains, by Dr. Francis G. Blake of New Haven, Sterling Professor of Medicine in the Department of Internal Medicine at Yale University School of Medicine, on "The Diagnosis and Treatment of Respiratory Diseases."

LORENZ J. BROSNAN, ESO. Counsel, Medical Society of the State of New York

Malpractice Action Barred by Release

With the continual increase of automobile accidents, and the proportionally great amount of care rendered by physicians to persons so injured, the outcome of damage suits brought by such persons is always a matter of interest to physicians. Treatment rendered to such persons has sometimes led to malpractice suits. Not until very recently. however, has the effect of a settlement between a patient and the person responsible for the original injuries upon such malpractice suits, been definitely established. The New York Court of Appeals has squarely passed upon that question in a case recently decided by it.*

On November 20, 1931, a small child was struck and run down by an automobile owned by one G. and operated by one F. The child was taken to a nearby hospital for treatment for her injuries, and her care came under the charge of M, one of the surgeons on the staff of that institution. The patient had a stormy course during her confinement, and remained in the hospital for several months, and during that time she underwent certain operations. On May 22, 1932, her condition had improved sufficiently that she was on that day discharged from the hospital and from the care of Dr. M.

Two days later the child's father had himself appointed guardian ad litem of the child, and during June 1932 he brought an action on behalf of the child in the Supreme Court to recover damages for the injuries sustained against F. and G. The father also brought a separate action against F. and G. for the loss of the infant's services and for the expenses he had incurred for her care and treatment. After that action had been started negotiations were entered into be-tween the parties to that action which resulted in August of that year in the settlement of the two actions. The settlement of the infant's action of course was made pursuant to an order of a Justice of the Supreme Court approving the settlement. At the time the order was so made the papers before the Court set forth the condition of the child at that time, and made reference to the care and treatment that the child had received. Thereupon the infant's action was settled by payment of somewhat

* Milks v. M., 14X Misc. 297, 264 N. Y. 267.

over \$3,000 to the guardian and the father's individual action was compromised by the payment to him of \$4,500. The father, pursuant to the Court's order as guardian ad litem executed a general release to F. and G. and also executed a similar release

to them in his personal action.

In December of the same year, after the settlement with F. and G. had been completed, the guardian brought another actionin the Supreme Court on behalf of the child, and on his own behalf as an individual, this time naming the doctor M. and the hospital as defendants. The complaint was that due to the alleged malpractice of M. and the alleged negligence of the hospital through its nurses and doctors, the plaintiffs \$100,000 were entitled to recover It was claimed that such negligence and malpractice prolonged and aggravated the original injuries, and also caused other injuries.

An application was made to the Court at Special Term, setting forth the foregoing facts, for a dismissal of the complaint as to the doctor on the grounds that the release of F. and G. released any rights of action against the doctor. The Court, (Mr. Justice Heffernan, now a member of the Appellate Division for the Third Judicial Department), granted the motion in favor of the doctor, and handed down a well written

opinion, which said in part:

Where one who has suffered personal injury by reason of the negligence of another exercised reasonable care in securing the services of a competent physician or surgeon and his in-juries are thereafter aggravated or increased by the negligence, mistake or lack of skill of such physician or surgeon, the law regards the negligence of the wrongdoer in causing the original injury as the proximate cause of the damages flowing from the subsequent, negligent or un-skilled treatment thereof, and holds him liable therefor. * * *

Conceding malpractice on the part of the defendant M. as charged in the complaint it seems to me that the plaintiffs are precluded from a recovery against him. F. and G. were liable not only for the injuries sustained by plaintiffs but also for the malpractice of the attending surgeon and for the expenses of medical attendance. Having that liability in view they settled with plaintiffs, paying them a substantial sum for a release from further liability At the time the release was given the child had left the hospital and had already suffered from

the alleged malpractice. These were all matters that could have been enforced against the original wrongdoers under their liability for damages and the settlement was clearly made with a view to covering all these elements of damage. They were known to exist by the parties to the release and the settlement was made with reference to them. In view of the fact that F. and G. were liable for the negligence of the defendant M. in improperly treating the child then the release included such damages and is a bar to the present action. The release having been made in full settlement of all existing claims precludes the plaintiff from bringing a second action for malpractice against the surgeon, occupying somewhat the position of a joint tort-feasor to recover double compensation. The fact that the plaintiffs now say that they did not intend to release M. is immaterial; a release of the original wrongdoers releases him regardless of the intent of the plaintiffs.

The plaintiff carried the ruling up on appeal and the Appellate Division without opinion affirmed the ruling of the Court below. The decision was one which involved a question of law never before actually passed upon by our higher Courts, and the case finally reached the Court of Appeals. That Court came to the same conclusion and affirmed the previous rulings. Its opinion written by Judge Lehman stated in part the following:

The general release of all claims against the original tort-feasors was made without reservation. A general release to one tort-feasor made without reservation creates a bar to an action for damages against another tort-feasor arising from the same injury. A physical injury sustained through the negligence of one person may be cured by the skill of a physician, or aggravated through his negligence. The negligence of the physician may then give rise to a cause of action against him, to recover the damages which the injured person would not otherwise have sustained. It may be argued that the original wrongdoer who caused the injury and the physician whose negligence aggravated the injury are not, in technical sense, joint tort feasors. Nevertheless their wrongs coalesced and resulted in damage which would not have been sustained but for the original injury. A wrongdoer is responsible for the proximate result of his wrong. What constitutes a proximate result is not a problem of stitutes a proximate result is not a protein of philosophy. "The law solves these problems pragmatically." Fortiuitous circumstances may divert the flow of cause to effect from its natural course. New streams of greater volume and force may join the flow. Liability for damages caused by wrong ceases at a point dictated by public policy or common sense. In some situations the courts have established a definite rule of limitation. In others the test is one only of degree. The rule is now well established that a wrongdoer is liable for the ultimate result, though the mistake or even negligence of the physician who treated the injury may have in-creased the damage which would otherwise have followed the original wrong. In such case satisfaction by the original wrongdoer of all damages caused by his wrong bars action against the negligent physician who aggravated the damage. The law does not permit a double satisfaction for a single injury.

Subsequently the ruling was held to apply equally to the hospital by the Court at Special Term. The opinion upon that ruling included the following language:

The rule applicable to the defendant M. must likewise be applicable to the defendant hospital. Prior to the compromise and settlement and prior to the commencement of this action the plaintiff had left the hospital, and the settlement was necessarily based on her then present condition. The original wrongdoers F. and G. were the cause of the infant plaintiff going to the hospital and remaining there as a patient. Whatever her condition may have been at the time of the settlement was due primarily to the accident. Whatever transpired at the hospital was before the court and was considered in arriving at the amount of damages.

The justice of the rule established by this case seems apparent. There must be some degree of finality to litigation. If the rule had not been so established, many persons injured in automobile accidents after collecting for their injuries from the parties originally responsible, might thereupon, having found themselves successful thus far, greedily and unjustly seek to collect more money for themselves from the very doctors who had been the cause of their being healed of their injuries.

Removal of Superfluous Hair

The plaintiff, a young unmarried girl, consulted a physician complaining of hair on her face. He found that she had what amounted to almost a complete beard on her face, chin, and neck. She told the doctor she had previously undergone electrolysis treatments at a beauty parlor. He decided to administer further electrolysis treatment to her and did so intermittently from time to time over a period of about two years. During the treatment certain keloids formed on her face and the doctor treated them from time to time with applications.

Subsequently an action was brought against the doctor charging that improper treatment on his part had caused the development of the keloids. The case came on for trial and the claim was made by the plaintiff that he had continued electrolysis treatment in the region of the keloid but the doctor denied that he had done so.

At the conclusion of the entire case the Court dismissed the plaintiff's complaint thereby exonerating the doctor of the charges which had been brought against him.

Across the Desk

Opportunity With a Big O for Medicine

As you READ these lines, thousands of enumerators are busily going from house to house in city and rural areas all over the land, to discover the extent of disabling illness that exists, and to find how much of it has had medical, nursing, and hospital care. Probably nothing that the government has ever done has been fraught with greater possibilities to the medical profession, for good or ill.

In our own State, the entire populations of Hudson, Newark, Penn Yan, and Schenectady are being canvassed, and portions, or "samples," of New York City, Buffalo. and Syracuse. The number of physicians. nurses, hospitals, and other health facilities in every region are already a matter of record, and need no special inquiry by the gentlemanly and ladylike canvassers recruited from the "white-collar" members of our great army on the relief rolls. When the extent of disabling illness has been found, and the amount of medical and nursing care is put alongside it for comparison, then we are to see what is needed to bring the health of the people to a better level.

It would seem a sure bet that a great amount of illness will be found to be without proper medical and nursing care, and Opportunity with a big O will be presented to the profession to render greater service. Instead of "too many doctors," we shall find that there are far too few. If our medical leaders are alert with plans to meet the situation revealed, then the schemes of the socializers will be thrown back upon themselves, like the fate of the horse doctor who tried to blow a laxative powder down the animal's throat through a quill. horse blew first! The brain trusters are reported ready to use the findings of the canvass as ammunition for their campaign for state medicine, but if the medical leaders "blow first," a sound plan may go through instead of a bad one. "Thrice blest is he who gets his blow in first."

To Dull Grim Reaper's Scythe a Bit

The thought back of the investigation is that the prolongation of human life from a forty to a sixty year expectation in our time has been mostly due to the conquest of the infectious ills of childhood. It is now proposed to study the causes of the chronic ailments and disabilities of middle life, often associated with occupation, habits, and financial position. The findings will give a basis of facts on which to build plans to prevent and control these chronic and disabling diseases. The canvassers are interviewing some 750,000 families in about ninety-five cities and towns, and a total of 5,000 to 6,000 persons are engaged in the work. The interviews are to be completed by March 15, then the statisticians will be turned loose on the huge mass of findings and will sort, file and index it so that we can know as a nation just how sick or well we are, what is the matter with us, how many of us have wooden legs or glass eyes. and how many have medical, nursing, and hospital care.

Statements of families that they have had this or that disease will be verified by asking their doctors, so that the data will have a certain scientific basis, and not be merely a loose record of ills that people imagine they had. The term "doctor" in this investigation, by the way, "is not limited to the medical profession," according to the official book of instructions to the canvassers, but "osteopaths, Christian Scientist healers, etc., are included. Do not raise the question of cults. Simply enter doctor as Dr. ——." This should be remembered in evaluating the returns when they appear.

"Disabling Illness" May Be Trifling

A "disabling illness" in this inquiry is defined as "one that keeps a person from working or from following his usual pursuit for at least a day." If a cold keeps a child at home from school for one day, that is entered in the returns as a "disabling illness." Many have supposed this term to mean an illness that makes work impossible for a long period, perhaps for life, but it appears that "for a housewife, it is an illness which keeps her from doing her usual housework." (sic.) A large number of the "disabling illnesses," therefore, may really be too trifling to need a doctor, a nurse, or a hospital, and the public should not be

stampeded into a belief that a mass of tragic suffering is going without medical attention A "disabling illness" of seven or more days duration is entered in another column, but we all know that such indispositions, too are often of slight importance

Hospital and institutional care, deaths, operations, missing fingers, legs or arms, deformity, paralysis, hernia, blindness, deafness, accidents in home, shop, or streets, canes, crutches, trusses, braces, artificial arms and legs, etc., are all entered in various Particulars about smallpox and diphtheria, vaccination and immunization, are jotted down Details about toilet arrangements are tactfully extracted family income is asked and set down and, rather oddly, the canvasser is required to find out if any member of the family is a veteran who ever served under the U S flag, his rank, and his pension or any compensation received from the U S Government for military service. Just what place this has in a national health inquiry is not stated

However, in all the maze of detail, the serious illnesses, too, will be listed in their appropriate places, and we shall, or should, learn how many of them had, or had not, medical and nursing attendance. The re turns will be public documents, and should be open to the inspection of all and no juggling or hocus pocus of the figures for political purposes should be permitted.

"Look Away Down South to Dixie"

ONE WIDEAWAKE STATE medical society, at least, is taking time by the forelock and is gathering material to defend its members against any attempt to regiment or socialize The State Medical Association of Georgia has been asking the U.S. Public Health Service for several years to make such a health survey as is now on, and it is completing the picture by a survey of Georgia physicians A questionnaire has been sent to every doctor in the state, asking if his practice is urban or rural, how long he has practiced medicine, his approximate net income approximate expense, approxi mate uncollected accounts, amount of charity practice value of medicines furnished free, county provisions, if any, to pay doctors for care of charity patients, county laboratory and hospital facilities, amount of post graduate instruction received, membership in county medical society, regularity of attendance, and suggestions for improving the health of his community and increasing financial returns from medical practice The officers of the name is to be signed State Medical Association, we are told hope to use this information when obtained to promote the interest and welfare of our members and the people without means to pay for adequate medical care. This survey may be of mestimable value to promote legislation which our profession sponsor, or to defeat legislation which might be to our detriment"

The "Sample Racket"

THE MORE WE LOOK into the trickery practised by certain unscrupulous drug stores, the clearer it is that the doctor, for his own protection and that of his patient, should see that his prescriptions are filled by chemists who carry honor and conscience as part of their stock in trade. If these are times that try men's souls, it must be said that many of the souls are giving way under the strain and deserve to have their next trial in the police court Amid all the "rackets" exposed day by day we now have the "sample racket," which is rousing condemnation in the medical and pharmaceutical It seems that hawkers have been going about, visiting doctors' offices and buying up from office boys or secretaries old samples that have been cluttering up desk drawers and closet shelves for anywhere from six weeks to six years The racket is so well organized, we are told that regular collections are made of bags at \$1 each and baskets at \$2, regardless of the ourlity of what is in them

The racketeers then take these old samples, perhaps mert or even injurious from age, freshen up the labels, change dates of expiration of potency, and sell them to the drug trade at discounts ranging from 25 to 50 per cent below legitimate prices. They are placed in with the regular stock and sold as fresh to the unsuspecting purchaser. When the patient fails to improve as expected, the doctor perhaps changes the prescription to another product, and another old sample may be handed out, with the same result.

This news may be an eye opener to some of our own readers, as the racket is reported flourishing in New York City and Brooklyn Chicago is also affected Interviews with

reputable pharmacists and medical manufacturers indicate widespread chicanery by conscienceless drug swindlers whose proper place is behind the bars, looking out. The victims are the doctor and his patient, and it is clearly to the doctor's interest to encourage the more honorable sort of pharmacists, who at least will be working with him, and not against him. The ethical chemist, too, is being run hard by these unconsionable scalawags, who are cutting into his trade terrifically, and, unless we wish the better grade of chemists to disappear, we must stand by them in this crisis.

Our "Era of Too Much"

It is possible that the fantastical times we live in may be known in future history books as "the era of too much." We have too many people for the number of jobs, and too much food for them to eat. We have "too many doctors," some say, yet too many people lack proper medical care. We have too much machinery, too many laborsaving devices, so the factories shut down and there is no work at all.

Malthus became famous because he proved that populations would grow to the point where they would encroach upon the means of subsistence, eat up all the food, and starve to death. Instead of that, we pay the farmers to plow their crops under and slaughter little pigs by millions because the markets are surfeited with provisions. Malthus was a clergyman, and his neat remedy for overpopulation was to persuade people to exercise marital self-restraint. The good man does not appear to have been entirely successful in this appeal, for in the 138 years since his book came out the population of England has quadrupled and that of continental nations like Germany and Italy has doubled. That is one explanation of Italy's raid on Ethiopa, to find a place for its surplus sons.

Over on the other side of the globe we see the same thing. Only a few years ago Japan's population was growing at the rate of half a million a year; a little later it was three-quarters of a million; now it is a full million a year. It is like a steam boiler, with the pressure going up, up, up. An explosion had to come, and we see the eruption overflowing Korea, Manchuria, and North China. All caused by too much. The statistical sharps inform us that the population of the globe has quadrupled in the last 300 years, and instead of slowing up, the increase is accelerating. Interesting times ahead.

Books

The Woman Asks the Doctor. By Emil Novak, M.D. Octavo of 189 pages, illustrated. Baltimore, Williams & Wilkins Company, 1935. Cloth, \$1.50.

In no other phase of medicine is it so easy to get the attention and capture the imagination of the lay reader, as on the subject of sex. And, in no other part of medicine is it so easy to make misstatements, gross errors, deliberate and gross exaggerations, and to indulge in purely imaginative meanderings. Little wonder, therefore, that the past ten years has seen the book market literally flooded with sex books of all shades and variety, each purporting to explain all phases of womanhood and fathoming the secrets of sex. Many of these are not authoritative, convey false information and are merely designed to be "sexy".

Indeed, very few books are there for the layman, which give authoritative information on such important topics as, menstruation, ovulation, menopause, sterility in women, the relation of the glands of internal

secretion to female function, etc., without the book becoming a sort of "laymen's textbook in gynecology". The publication, therefore of "The Woman Asks the Doctor", by Dr. Emil Novak, is a distinct contribution to the literature on the subject for the intelligent laity.

Being written by Dr. Novak, the book carries at once the stamp of authority and conservativeness. It is written in an easy, simple and interesting style. The author states repeatedly, that the book is not designed to be a miniature textbook in gynecology; and that for any abnormal symptoms or signs, that the reader consult her physician. The book covers the most important phases of woman, viz., puberty, menstruation, reproduction, sex glands, sterility, cancer and the menopause. Simple diagrammatic drawings illustrate the book throughout.

Every woman should own a copy and

read it several times.

J. HALPERIN

Diseases of the Mouth and Their Treatment: A Text-Book for Practitioners and Students of Medicine and Dentistry. By Herman Prinz, D.D.S., M.D., and Sigmund S. Greenbaum, M.D. Octavo of 602 pages, illustrated, Philadelphia, Lea & Febiger, 1935. Cloth, 2000.

Herman Prinz of the University of Pennsylvania has been recognized as a world authority on dental therapeutics and materia medica. He is therefore well fitted

for his task.

This book which has been especially prepared for the physician and dentist is a thorough compilation of all important information concerning diseases of the

mouth and their treatment.

It first gives a very good resume of the embryology, anatomy and physiology of the oral cavity. It then systematically describes the oral manifestations of metabolic disturbances, blood disorders, infectious diseases, skin diseases and parasitic and tropical conditions.

The chapters on the diseases of the tongue and salivary glands are very interesting and up to date as are those on the other parts

of the buccal cavity.

In addition there is a chapter on oral hygiene and prophylaxis, and one on therapeutic suggestions which should be very helpful to the practitioner.

In the entire book, the authors have endeavored to combine the viewpoint of the physician with that of the dentist, and have succeeded to treat the entire subject-matter as a medico-dental problem which it is.

There is no doubt that this book will fill an evident hiatus in the medical literature and the reviewer is very happy to recommend it very highly to the student and practitioner of medicine and dentistry.

OSCAR RODIN

Ideal Health or the Laws of Life and Health, By Alexander Bryce, M.D. Third edition. Duodecimo of 340 pages, illustrated. Baltimore, William Wood & Company, 1935. Cloth, \$2.00.

The author of this book—"Ideal Health"—has made an amhitious effort to keep his readers healthy with lots of rules that in themselves are, in the main reliable, but when taken collectively seem to so complicate the issue as to make the reviewer wonder how many of these rules the reader can or will observe, and to what extent he may benefit by observing all these rules. The plan of this book is dogmatic, and

The plan of this book is dogmatic, and each of the chapters is headed by a commandment—much like the ten commandments—which forms the basis for each sermon or chapter. The reviewer questions the wisdom of applying a biblical approach to things medical, especially when contours to the control of the control of the plant of the plant of the control of

troversial issues must often be faced and explained away. Moreover, the book is too lengthy and too detailed.

EMANUEL KRIMSKY

Arthritis and Rheumatoid Conditions their Nature and Treatment. By Ralph Pemberton, M.D. Second edition. Octavo of 455 pages, illustrated. Philadelphia, Lea & Febiger, 1935, Cloth, \$5.50.

This book presents a full picture of arthritis in all its phases by an author who has spent many years in a careful study of the disease. It is first discussed as an economic and social problem. The most frequent sites of focal infection in civilian life were found to be the dental, nose and throat and genito-urinary in the order named. The prostate is considered to be of importance.

The idea that allergic phenomena provide the mechanism for the arthritic symptoms is stated to have many supporters. The pathology of the two types, atrophic and hypertrophic, which are the terms preferred by the author, is fully discussed. He believes that it can not be concluded with absolute certainty that the two types are wholly discrete although clinical and pathological separation is justified and necessary.

The author's opinion as to the value of various forms of therapy is fully stated and diet and physiotherapy especially described in detail. He believes that it is not settled how much of the influence of vaccines, when helpful, is to be attributed solely to a specific influence and how much to a more generic reaction, possibly of the nature of a non-specific protein reaction. Throughout, the book will be found to be an authoritative and conservative guide to the subject.

W. E. McCollon

Recording of Local Health Work. By W. F. Walker, Dr. P. H., and Carolina R. Randolph. Quarto of 275 pages, illustrated. New York. The Commonwealth Fund, 1935. Cloth, \$2.00.

This volume is of particular interest to health officers. As emphasis is being placed at present on the fact that the practicing physician is "The Utimate Health Officer" it may interest him to note how records should be kept for purpose of easy and fair comparison. Unless facts are based on similar premises they cannot be compared. At least half of the subjects that are considered concern communicable diseases and matters of individual hygiene-all subjects of practical importance to the general practitioner in his daily work. The records suggested are simple and concise; if used generally by the health officers a proper evaluation and comparison of health work will be possible. A. E. SHIPLEY

Physiology in Modern Medicine. By J. J. R. MacLeod, M.B. Seventh edition. Octavo of 1154 pages, illustrated. St. Louis, C. V. Mosby Co., 1935. Cloth, \$8.50.

MacLeod's Physiology has been a standard text book since its first edition appeared in 1918. It is unfortunate that, MacLeod, a great master of physiology, a Nobel prize winner for his role in the discovery of insulin, and a leading contributor to the physiology of metabolism has recently died. He did not live to see the last (7th) edition of his book off the press. He has in this volume received the cooperation of such physiologists as Bard, Carter, Olmsted, Peterson and Taylor. It is natural that the section on metabolism should comprise almost a third of the book. It is of course presented authoritatively, for the author and his pupils have added a good portion to our present day knowledge of this subject.

The book will undoubtedly remain an important text and reference book in general physiology for some years to come.

WILLIAM S. COLLENS

The Diseases of the Endocrine Glands. By Hermann Zondek, M.D. Third edition. Octavo of 492 pages, illustrated. Baltimore, William & Wilkins Company, 1935. Cloth, \$11.00.

Zondek's endocrinology, published years ago in Germany and brought up to date for its present translation, is an important book. It is written by a man who has contributed substantially to the advancement of endocrinology both as a laboratory investigator and as a clinician. While his eminence as a research worker should not be minimized, his real field and acknowledged predilection is in the line of clinical diagnosis and therapy. His treatise is primarily the contribution of the physician for whom the endocrine glands are not organs apart, but components of the whole body, both influencing the latter and partak-ing in its reaction. Thus endocrinology appears as a part of internal medicine, while medicine cannot be practised intelligently and progressively without a thorough understanding of endocrine physiology and pathology.

Zondek's work differs fundamentally from other contributions on the subject by his arrangement of the material according to diseases, independent of their glandular origin. Lead by the conviction that all other glands participate in the disorder in the majority of the cases, discussion under the heading of one, albeit the most prominently involved gland, does not seem

warranted.

Some of Zondek's basic tenets are cited in his preface and are well worth to be born in mind as guiding thoughts in the confusing mass of observations on endocrine patients. Thus according to Zondek: 1./ a hormonal effect is not an absolute but a variable quantity, depending upon the momentary physico-chemical condition of the cells on which it acts; 2./ changes of endocrine glands are not always the cause of disease but in many cases the reaction to morbid processes primarily located in other organs; 3./ the endocrine system is but one link in the chain of vegetative functions of the organism.

Zondek's book was not written for the needs of the general practitioner; it contains perhaps more theory than the busy practising physician has time to digest. It serves admirably the purpose of the man who specializes in internal medicine, yet was unable to devote detailed studies to the problems of glandular physiology and pathology. Stimulating to thought and full of challenging ideas it will be appreciated most by the student of endocrinology.

M. A. GOLDZIEHER

Physical Diagnosis. By Warren P. Elmer, M.D. Seventh edition. Octavo of 919 pages, illustrated. St. Louis, C. V. Mosby Co., 1935. Cloth, \$8.00.

This book is divided into two parts. Part I deals with the technic of physical examination including a section on normal electrocardiography and radiology in physical diagnosis. This section is well presented and profusely illustrated. It is rather surprising that ten pages are devoted to polygraphy. Herpes is mentioned as occuring in typhoid fever contrary to the usual experience. Under myosis the action of morphine on the pupils is omitted, under blue scerla fragilitas ossia is not mentioned and under bilateral ptosis no mention of myasthenia gravis is made.

Part II includes diseases of the respiratory and circulatory system. This section is

excellent, concise and complete.

The clinical pathology, physical signs, diagnosis and differential diagnosis are well presented, including the radiographic diagnosis.

On the whole this latest edition of this work is a worth-while addition to the

student's and practitioner's library.

HENRY JOACHIM

Martini's Principles and Practice of Physical Diagnosis. By Robert F. Loeb, M.D. Duodecimo of 213 pages, illustrated. Philadelphia, J. B. Lippincott Co., 1935. Cloth, \$2.00.

This small volume of about two hundred pages is an excellent presentation of physical signs, their significance, interpretation and mechanism. The book can be recommended to the medical student as an elementary exposition on physical diagnosis, and to the practitioner of medicine for a hasty review and brushing up.

Henry Joachim

NEUROSY IHILIS

A spinal fluid examination is advocated in all cases of syphilis, for by this means early serologic changes, indicative of a pre-disposition to neurosyphilis, may be detected, and proper treatment instituted.

The use of Tryparsamide Merck is an office procedure. It is administered intravenously, does not disrupt the patient's daily routine of life, and is

Difference in Cigarettes vs

Difference in Effect

To CLAIM merely a difference in cigarettes is, obviously, not enough—this difference to be of value must be shown to produce an advantageous difference in effect.

Philip Morris cigarettes not only are made different, but because of that difference have been shown by scientific proof measurably and significantly less irritating than ordinary cigarettes.

Proc. Soc. Exp. Biol. and Med., 1934, 32, 241-245 Laryngoscope 1935 XLV, 149-154 N. Y. State Jour. Med. 1935, 35—No. 11,590★

In Philip Morris cigarettes, only diethylene glycol is used as the hygroscopic agent. To any Doctor who wishes to test the cigarettes for himself, the Philip Morris Company will gladly mail a sufficient sample on request below.**

FOOD-DRINK ADDS AVAILABLE IRON TO THE DIET!

ALSO RICHLY PROVIDES CALCIUM, PHOSPHORUS AND VITAMIN D

COCOMALT, the delicious chocolate flavor fooddrink, is a rich source of available Iron. An ounce of Cocomalt (which is the amount used to make one cup or glass) supplies 5 milligrams of Iron in easily assimilated form.

Thus three cups or glasses of Cocomalt a day supply 15 milligrams — which is the amount of Iron recognized as the normal daily requirement.

Used as a delicious food-drink, Cocomalt provides a simple, palatable means of furnishing Iron to growing children, convalescents, expectant and nursing mothers.

... and for bones and teeth

In addition to Iron, Cocomalt is rich in Vitamin D—containing at least 81 U.S.P. units per ounce. Cocomalt is fortified with Vitamin D under license granted by the Wisconsin Alumni Research Foundation.

Cocomalt also has a rich Calcium and Phosphorus content. Each cup or glass of this tempting food-drink provides 32 gram of Calcium and 28 gram of Phosphorus. Thus Cocomalt supplies in good biological ratio three food essentials required for proper growth and development of bones and teeth: Calcium, Phosphorus and Vitamin D.

Easily digested – quickly assimilated

Not the least of Cocomalt's many virtues as a food-drink is its palatability. It is so refreshing, to delicious it and the company of the very sick. And high nutritional l, quickly assimi-

lated, imposes no digestive strain.

Recommended by you and taken regularly, Cocomalt will no doubt prove of great value to many of your patients.

FREE TO DOCTORS

We will be glad to send a professional sample of Cocomalt to any doctor requesting it. Simply mail this coupon with your name and address. Gcomali ...

Cocomalt is the registered trade-mark of the R. B. Davis Co. Hoboken, New Jersey.

CHARLES B. TOWNS HOSPITAL

FOR THE EXCLUSIVE TREATMENT OF

ALCOHOLISM and DRUG ADDICTION

This hospital has specialized solely in addictions for over thirty years. Our experience has shown us that best results could not be obtained when associated with any other type of case. method of treatment has been fully described in the journal of the American Medical Association and other scientific literature. The treatment is a hospital procedure and provides a definite means of eliminating the craving and the toxic products of alcohol and drugs. Emphasizing the after care and with appreciation of the seriousness of the alcoholic problem we devote the convalescent period to minimizing the possibility of relapse. In the classification of the City of New York hospitals this institution has been granted a special license by the Commissioner of Hospitals for the exclusive treatment of alcoholic and drug addiction.

Plan Now to Attend the 1936 Convention

the SECOND or EXERCISE PERIOD

"Physical exercise, in its various forms, including sports and gymnastics, as well as the use of cold water treatment, are important ingredients of the second period . . ."

This is practiced therapy that you are familiar with, especially in cases where in addition to the physical benefit of exercise there is important psychic influence-strengthening of will power by making the patient do the things that help alleviate phobias and obsessions.

The Health Roof, the most completely equipped establishment of its kind, is your "treatment" when exercise is indicated-for "self-medication" in such cases is obviously as inefficient as "home-remedies" in serious illness. We, therefore, recommend our facilities, experience, and trained staff as assurance of a patient's following your dictates and of our strict cooperation.

A Guide to Select Schools

Schools of refinement selected particularly for a high rating in efficiency and culture.

MILITARY ACADEMY a BIG school FOR little BOYS

In a class by itself. First to eighth grades, Modern fire-proof buildings, acres of play grounds, sports facilities. Unex-celled faculty, Twenty-eighth year. Resident or day pupils admitted any time. For catalogue, etc., write Major R. A. Gibbs, 1249 So. Cochran Ave. Los Angeles, Calif.

The Father's Biggest Business

A lot of investments have gone bad in recent years. Real estate has lost much of its reality; securities have proved insecure; bonds have led us into bondage. But no slump can depress the value of funds invested in the boys and girls, to make them fine, strong worthwhile men and women. As Daniel Webster said:

"If we work upon marble it will perish. If we work upon brass, time will efface it. If we rear temples, they will crumble in the dust. But if we work upon immortal souls, if we imbue them with principles, with the fear of God and love of our fellowmen, we engrave on those tablets something which brightens all eternity."

The father's biggest business is to see that his sons and daughters are heading in the right direction. The director of a great school makes this appeal to fathers under the heading: "That boy of yours!"

"When he first saw the light of day he was the most wonderful thing in the world. You told yourself that you and he would always be pals. Now suddenly emerging LABORATORY TECHNIQUE

An uncrowded profession offering steady, dignified, highly remunerative employment. Complete course including clinical laboratory technique and basal metabolism in six months. Small classes with personal supervision. A splendid course for post graduate work. Student dormitory maintained. For information write for catalogue.

Eastern Academy of Laboratory Technique, 1709 Genesee St., Utica, N. Y.

The Foremost School of Laboratory Technique prepares High School Graduates for this intensely interesting, well paying work in hospital or physician's laboratory. Newly improved course in laboratory technique increased to 9 months. Complete course, including X-Ray and physical therapy

one year.

from your own affairs, you are faced with the realization that he is growing up-that he and you are out of touch. Your boy is your greatest business. The years between ten and twenty mark the turning of the tide in a boy's life. Then boys often think parents unreasonable, harsh, unsympathizing. Parents often think boys secretive, callous and unresponsive. Left to chance, a boy in his teens may become anything. A mistake may be fatal. A really great school may save him, for it is engaged in the greatest business in the world—the making of men."

"PASSED A HUNDRED PER CENT AS A SANCTUARY TO: HAY-FEVER SUFFERERS"

This survey included a thorough inspection of the plant forms active in August, a careful study of flora active at other times, and interviews with disinterested persons. Professor Hodgson's findings were published in a report which gave new official confirmation of an old truth about Bermuda. To quote from his report: "... the Colony passed a hundred per cent as a sanctuary for hay-fever sufferers."

Frost, too, is unknown in these lovely coral islands. And motor traffic, smoke, and clamour.

Instead, visitors here find a favourable climate the year around. They find splendid golf courses; game-fishing; sailing; tennis courts of turf and en-tout-cas; they find warm beaches of pink sand, and crystal-clear surf for invigourating sea-bathing even while the far-off New York skyline is blurred by cold wind and sleet. Bermuda, in short, is an unsurpassed, twelvemonths-in-the-year source of those two treasures—Pleasure and Health.

Mark Mary

The control with the wife Market The

"BUT CAN I AFFORD BERMUDA?"

•The inexpensiveness of a trip to Bermuda always astonishes those making their first visit. Round-trip passage (with private bath) on a luxurious liner costs as low as \$60 for four joyous days at sea. In Bermuda you can secure a splendid room and excellent meals for \$7 a day.

Travel and Hotels

For Washington's Birthday

The first week-end holiday this year comes as a rather welcome treat with undoubtedly a milder weather condition suggesting the approach of Spring.

For those of us with sea-faring inclinations, several cruises are offered among which the most outstanding will be the Bermuda Cruise of the United States Liner Manhattan and one scheduled for the "Oueen of Bermuda" of the Furness Bermuda Line.

The cruise of the Manhattan is for four days and this splendid steamer is so well known that it is hardly necessary to describe its de luxe cabins and other rooms, its dining rooms and cuisine, sports decks, cafes, etc. Rates for the cruise begin at fifty dollars.

The special holiday cruise of the "Oncen of Bermuda" is for four days with a stopover in Bernuda and ample time to enjoy that island's sports and social activities. Optional stopovers in Bermuda on a special arrangement of eight, eleven and fifteen day all-expense trips are also available. Special programs of entertainment are provided. Large dance floors. enclosed and tiled swimming pools, movies, wide sports decks, an excellent cuisine, and gymnasiums are a few of the special features that contribute to the pleasure of the cruise. Every stateroom, even at minimum rates, is equipped with a private bath.

For those of us who have to stay within a few hours' ride home, the Atlantic City and Lakewood, N. J., hotels are offering specials for the holiday. At Atlantic City, elaborate prepara-

tions are being made by the hotels and amusement centers especially for Washington's Birthday. The outstanding feature of that weekend will be the annual ice carnival to be held at the Convention Hall on Saturday evening, and which is under the direction of the Philadelphia Figure Skating Club and sponsored by the Morris Guards, Atlantic City's

civilian-military organization. A Scandinavian

setting will be the predominating note throughout the pageant with the participants costumed

in brilliant native attire characteristic of the

"Land of the Midnight Sun."

A Record Exodus to Florida

When the familiar cry of the Stationmaster "All Aboard" rang through the Pennsylvania Station at 2:05 P. M. on January 31st, an unprecedented crowd of Florida-bound travelers surged forward looking for their transportation -the first step toward a place in the Sun.

Five sections of the "Florida Special" of the Atlantic Coast Line were required to handle the heavy Florida traffic on that day.

This establishes a record for train travel to a given resort section, as, according to R. S. Voigt, General Eastern Passenger

Telephone—Circle 7-5679

(Continued from page xxxiii)

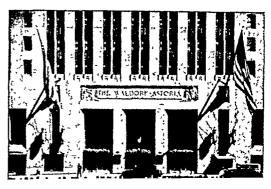

Agent, within four days not less than sixteen heavy sections of the "Florida Special" were required for the run to Miami.

The popularity of this train is accredited in a large measure to the Recreation Car, with music, dancing, bridge, etc., all supervised by a charming hostess, who makes the 27¾ hour trip from New York to Miami a most enjoyable one.

Your 1936 Convention Headquarters

As this year's Annual Convention of the Medical Society of the State of New York promises to be not only the largest in this Society's history, but no doubt the biggest gathering of physicians and surgeons here in the East this year, points of interest about the official headquarters and the great city in which the convention is to be held will be of interest to every member.

The site of the Waldorf-Astoria, still a new hotel to many of us who haven't been a guest there since it was located where the

Empire State Building now stands, is an ideal location for it is practically in the center of things.

Three minutes away (counting in a measure of time) is the Grand Central Terminal, the door to the entire state, while the Pennsylvania's terminal through which many of our guests will come, is only fifteen minutes away. The Waldorf-Astoria is also convenient to shopping districts and amusement centers. It is next door to Fifth Avenue, and a stone's throw from Rockefeller Center, New York City's newest and most interesting attraction. Eight minutes takes you to Times Square and the Great White Way with its hundreds of theatres and night clubs. Fifteen minutes take you to downtown Manhattan, the financial district, Bowling Green and the Battery, and a thousand and one things that compose an invitation to spend extra days in the city.

The Waldorf is a great center of New York life, not just because of its convenient location, but also because of its distinguished functions. Throughout the entire year it presents an ever-varied, always exciting picture of metropolitan life. In the Summer, New York dines and dances on the Starlight Roof. During the Fall and Winter months, the Empire Room is the gay world's favorite rendezvous for dancing and entertainment. The Grand Ballroom is the gracious background for different forms of entertaining; perhaps one day a huge business gathering, and the same night it is quickly transformed into fabulously lovely setting for a ball or great banquet. Concerts, musicales, fashion shows, teas, group meetings, and lectures are staged in the charming smaller entertainment suites. And in the delightful restaurants and bars, fine food is enjoyed while such artists as Henry King, Raul and Eva Reyes, Xavier Cugat, Georges and Jalna, Horacio Zito, the Lombardo Brothers, Veloz and Yolanda, and other famous musicians and stars entertain

At the convention, the Grand Ballroom is to be the scene of the General Scientific Sessions, Business Sessions, and the great banquet that ends the three days of activity. The Basildon Room, Jade Room, Astor Gallery, East and West Foyers, will house upward of one hundred and forty technical exhibitions which this year will lend tremendous interest in many new things in products and services. Scientific exhibits will have equally distinctive quarters and many interesting displays are being arranged.

All in all, everything points to some very excellent work on the part of the committees responsible for the success of the convention in the selection of the headquarters with its ample room for a meeting of thousands, and for all the arrangements being made.

Clinical Surgeons to Tour Europe

An interesting item gleaned from Travel Trade announces that the Southern Society of Clinical Surgeons will make a tour of Europe this summer in celebration of its tenth anniversary, with Thos. Cook & Son—Wagons-Lits Inc. who will be in charge of all arrangements for land travel in Europe.

The group will sail from New York in the St. Louis on June 6th for Galway, Ireland, where the tour will start. Ireland, England, Scotland, Norway, Sweden and Denmark will be visited and during the trip, clinics are being arranged in Dublin, Liverpool, Edinburgh,

The tour will end at Gothenburg, Sweden, where the tour party will embark on July 13th in the *Gripsholm*, which is due to arrive in New York, July 21st.

Travel Bill in Congress Will Stimulate More Domestic Travel

Glenwood J. Sherrard, Chairman of Travel Committee, American Hotel Association, writes: "After having spent a great deal of time during 1935 in helping the passage of the so-called Travel Bill through the tortuous halls of Congress, it would be strange indeed if I were anything but hopeful of the future outlook for travel.

"The committees from both the Senate and the House of Representatives were very much interested in the facts we presented in an effort to show the U. S. Government why it should establish an official Travel Propaganda Bureau of some sort, and appropriate funds to stimulate the tourist movement both to and within our borders. The bill has already passed the Senate, and will come up in the House at the present session. We are quite confident that it will receive the final seal of approval.

"As a hotelman, I naturally look forward to the inevitable benefits which will accrue to my industry, but the fact remains that an increase in travel will help our entire economic life. Railroads, hotels, steamship lines, retail merchants and manufacturers—and yes, even travel agents, will gain. For travel agents, in fact, a government-sponsored 'See America First' campaign may be the means of attaining the long sought-for reaproachment with the railroads, because such a development will give agents an opportunity to prove conclusively that they are creators of travel, and that they are entitled to commissions.

"So here's to the Travel Bill—soon may it pass!"

WM. H. PARKER President and Managing Director

"By the Holiday Camping Coaches Plan you may rent a home-on-wheels at selected sites in the country and at the seaside, when you buy your holiday tickets. The plan, inaugurated last Summer, provided an initial 200 such homes and was highly successful. The homes, complete in every detail, are converted railway coaches, run to their sites on short spurs from the main lines.

"A special Cruise Train for the Boy Scouts, in addition to the regular Cruise Trains and Land Cruises, was another of the Summer's innovations."

Red Cross Vessel Launched for Newfoundland Service

Red Cross Line's second vessel, the Fort Townshend, specially constructed for the New York-Newfoundland trade, has been launched at the yards of the Blythewood Shipbuilding Company, on the Clyde, according to advices received at the New York offices of Furness Withy & Company, Ltd., operators of this and numerous other services. The flagship of the fleet, the Fort Amherst, was launched last October and is expected to enter service from Halifax shortly. Both vessels are expected to enter New York-Newfoundland trade furnishing regular passenger and cruise service between these two points.

Accommodations are provided in each of the two ships for eighty-five first class and twentyeight second class passengers, with all modern conveniences for comfort and safety at sea. A number of spacious public rooms are also provided.

A feature of the new vessels is the large amount of refrigerated space provided for the handling of fruits, berries, vegetables and chilled meats. Both the Fort Amherst and the Fort Townshend are fully equipped with every known aid to navigation and it is expected that they will be the most efficiently operated vessels of their size. They are 310 feet long, with a forty-five foot beam, and will maintain an average speed of fourteen knots under normal conditions.

Travel Brevities

In Austria—through the generosity of an American, Mr. Irving Mayer, a new heart clinic has been opened in Vienna. Dr. Richard Singer will be chief-of-staff.

The International Dental Congress will take place in Vienna from August 2 to 8. A large delegation from the United States will be

present at the Congress for which an elaborate program supplemented by extensive entertainment for the delegates and their families has been arranged.

Between May 28 and June 2nd, the International Congress of Catholic Physicians will meet here. Among other pertinent topics slated for discussion are eugenics and sterilization.

THE HONORABLE THOMAS D. TAGGART, Recorder of Atlantic City, is using a very novel procedure in dealing with local speeders by having "Skull and Crossbones" stickers placed on the windshields of the cars of those found guilty. This "branding" will doubtless be an effective reminder of the consequence of "loose" driving both to the offender and the general public.

Doctors stopping at the Hotel Langton in Bermuda are, Alfred Narrath and Heroge Hirschfield of New York City, and their wives.

CIRCLE TOURS OF FLORIDA start any day up to April 15th. These tours cover eight days through the sunny state of Florida by rail and bus, and one feature is the assurance of hotel accommodations at fixed rates. American Express Travel Service renders this unique travel aid.

Bermuda, according to steamship passenger lists, continues to receive many doctors and their families. Recent sailings on ships of the Furness Bermuda Line had Dr. and Mrs. D. B. Thorpe of Boston and others aboard.

ABOARD the Northern Prince of the Furness Prince Line, arriving at New York, was the prominent Brazilian, Dr. Antonio Alvaro Assumpçao.

THE BELMONT MANOR and Country Club of Bermuda announced the arrival of the following doctors during January: Dr. R. H. Breslin of Providence; Dr. James A. Dumas of Lynn, Mass.; Dr. Oscar C. Frundt of Jersey City; Dr. F. G. Jensen of Wisconsin; and Dr. Robert H. Veitch of Medford. Mass.

AT THE HOTEL HAMILTON in Bermuda, the following doctors were guests: Dr. and Mrs G. E. Snider of Yonkers; Dr. and Mrs. Henry Sangee of Philadelphia; and Dr. E. A. Y. Schellenger of New Jersey.

ELBOW BEACH Hotel at Paget, Bermuda, numbered among their guests Dr. and Mrs. Victor Baer, Dr. and Mrs. L. Rotheld, and Dr. and Mrs. Jos. Sommer, all of New York State; Dr. and Mrs. H. J. Greene of Cleveland; Dr. and Mrs. L. R. Hess of Ontario, and Dr. and Mrs. Richard M. Rogers of Newark, N. J.

These tours cover eight days sunny state of Florida by rail one feature is the assurance of delaions at fixed rate. American

Maintain Mineral Alkali Balance

WITH

Kalak

Hypertonic-Alkaline-Carbonated-Not Laxative

The years of experience with physicians who have used Kalak show that the use of a formula containing calcium, magnesium, sodium and potassium salts represents a correctly balanced solution. This is Kalak which, as such, aids in maintaining a balanced base reserve.

How Alkaline Is Kalak?

One liter of Kalak requires more than 700 cc. N/10 HCl for neutralization of bases present as bicarbonates. Kalak is capable of neutralizing approximately three-quarters its volume of decinormal hydrochloric acid.

WHERE THE SLIGHTEST DEFECT SHOWS UP LIKE AN AIRPORT BEACON!

Altogether new standards in uniformity and keenness are set by the new improved A.S R. Surgeon's Blades. These remarkable blades are individually tested under tell-tale scientific equipment. Here the slightest defect flashes its warning to skilled examiners. Four separate inspections insure the absolute uniformity that aids swift, easy operation.

Developed after months of research during which eminent authorities were daily consulted, A.S.R. Blades are considered by noted surgeons to be the finest ever available for surgical use. First trial will demonstrate their superiority. Available in all 9 types – 6 blades to a package. Order from your surgical supply house.

Try their keener edges with our compliments-check the coupon for desired blades.

WHEN YOU DON'T WANT ADHESIVE TAPE TO STICK . . .

Use ADHESOL . . . this new idea in removing all types of adhesive tape and plaster saves you time and trouble, and ends discomfort to the patient—no matter how tender or hairy the skin.

ADHESOL instantly dissolves the adhesive compound — the tape peels gently off. No danger of tearing the skin and opening new sources of infection. After using Adhesol, the skin is left clean, soft and free of gum or stickiness.

ADHESOL has been proved by test far superior to unapproved, makeshift solvents, such as benzine, gasoline, etc., which frequently cause irritation. Adhesol has a pleasant odor which quickly disappears. It acts quicker and goes 6 to 10 times further than any other non-offensive solvent.

Your regular dealer sells Adhesol. If he cannot supply you, send one dollar for large bottle.

When a Liquid Vasoconstrictor is Indicated

Prescribe a Truly Economical Vasoconstrictor

Your patients will appreciate the very moderate prescription price of Benzedrine Solution—one of the least expensive of liquid vasoconstrictors.

But the physician realizes that true economy is measured in terms of something more than price alone. . . And Giordano has shown that "Benzedrine in a 1% oil solution . . . gave a shrinkage which lasted approximately 18% longer than that following applications of a 1% oil solution of ephedrine." (Penna. State Med. J., Oct., 1935.)

Scarano previously reported (Med. Record, Dec. 5, 1934), "The secondary reactions following the use of Benzedrine were less severe and less frequent than those observed with ephedrine."

BENZEDRINE* SOLUTION

AN ECONOMICAL VASOCONSTRICTOR

For shrinking the nasal mucosa in head colds, situatitis, and hay fever. Issued in I ounce bottles for prescription dispensing, and in 16 ounce bottles for office, clinic and hospital use.

* Benzyl methyl carbinamine 1% in liquid petrolatum with 1/2 of 1% oil of lavender.

Lobar Pneumonia and Serum Therapy

FREDERICK T. LORD, M.D.

Clinical Professor of Medicine, Emeritus, Harvard Medical School; member of the Board of Consultation, Massachusetts General Hospital; member of the Massachusetts Advisory Committee on Pneumonia.

RODERICK HEFFRON, M.D.

Field Director, Pneumonia Study and Service, Massachusetts Department of Public Health.

This handbook discusses fully the use of antipneumococcic serum in the treatment of lobar pneumonia, with special attention to the clinical diagnosis of the disease, the selection of cases for serum treatment, identification of pneumococcus type, technique of administering the serum, precautions to be observed, possible reactions and their treatment, and the results of serum therapy.

Recent experience has shown that serum can be given advantageously by general practitioners in the home, under the conditions set forth in this book. In treated cases there has been a reduction from the usual 25 per cent mortality to 11 per cent in Type I cases and from 41 per cent to 27 per cent in Type II cases.

The handbook is based upon experience with hundreds of cases over a period of several years.

Enlightening the World

Advertising is like that colossal bronze statue "Liberty" which dominates the harbor of New York—"Enlightening the World." The illuminating rays of advertising reveal what is best to buy—and where to buy it.

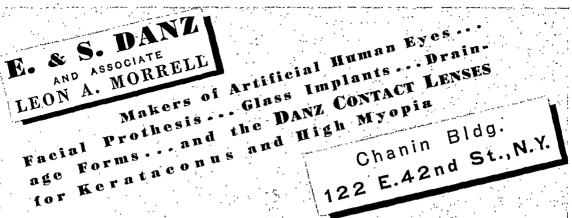

Advertising provides knowledge of the market and gives the buyer greater liberty of choice.

The publicity of advertising spurs the producer to give the highest possible quality for the lowest possible figure.

Competition created by advertising tends to make business open and above-board, raising American standards to a higher place—just as that for which the famous Statue stands has made this nation the envy and admiration of the whole world.

And just like "Liberty Enlightening the World"—advertising in the New York STATE JOURNAL OF MEDICINE is intended to enlighten the physicians of New York State as to products and services most valuable, practical, and reliable.

Watch the "ad" pages to keep informed—regular advertisers are a flaming torch lighting your way to knowledge and profit.

The World's Most Famous Natural Alkaline Water

PRESCRIBED BY PHYSICIANS THE WORLD OVER

VICHY CÉLESTINS, the most famous of natural alkaline mineral waters, is indicated in stomach and liver affections and digestive disorders in general; in gout, arthritis associated with uric acidemia, uricemia, and nephrolithiasis of uric acid origin. During convalescence, it eases and expedites the journey back to health. Vichy Célestins is obtainable everywhere.

BOTTLED ONLY AT THE SPRING IN VICHY, FRANCE

The Story of MEAD'S OLEUM PERCOMORPHUM

A NEW, ECONOMICAL, POTENT SOURCE OF NATURAL VITAMINS A AND D

OLEUM PERCOMORPHUM, or Percomorph Liver Oil, is the achievement of an intensive, 10-year investigation conducted in the research laboratories of Mead Johnson & Company to find a natural oil more potent in vitamins A and D than cod liver oil and less expensive to the

patient.

The U.S. Pharmacopoeia (IX, 1916, and X, 1925) recognized cod liver oil as the oil from the livers of fishes of the family Gadidae. There being some 50 species in this family, in addition to the type species, *Gadus Morrhua*, our first studies were directed at the examination of the more important species classed as cod. It occurred to us that somewhere in nature there might exist a species, or a family, or an order of fish, the liver oil of which would make possible a mixture comparable with Oleum Morrhuae but higher in vitamin potency.

The study was then directed to other species. By 1927 we had quantitatively compared the antiricketic value of oils from 15 species of fish and 11 other oils and fats. This was the most ex-tensive survey of vitamin D sources reported up to that time. Outstanding in this list was puffer fish liver oil with a vitamin potency 15 times that of cod liver oil. Puffer fish were not available in commercial amounts, but the fact that one species of fish yielded so high a vitamin store provided great stimulus to investigators.

We discovered that the potency of fish liver oils increases with the leanness of the livers. With this revelation, we began a survey of all available commercial fish, as well as of rarer species. Collectors were sent to distant continents and to the islands of the Pacific and Atlantic oceans. From ports which never before knew cold storage we arranged to obtain refrig-erated livers for our experiments. This ichthy-ological survey was interrupted (1928) at the time we introduced activated ergosterol. In 1929 the Norwegian investigator, Schmidt-Nielsen reported belief liver sid to be reported

Nielsen, reported halibut liver oil to be superior to cod in vitamin A. Upon investigating, we felt then, as we do now, that while halibut liver oil marked a distinct advance it left much to be

desired since it was perforce an expensive source of vitamin D. Hence it came to be used chiefly to supply vitamin A as a vehicle for viosterol.

Continuing the search for fish liver oils, by 1934 our laboratory staff had made thousands of bioassays of oils from more than 100 species to determine their vitamin characteristics. The results, reported in scientific journals in January and April 1935, were the culmination of a search literally of the seven seas.

With cumulative data on more than 100 species, it became evident that the fish belonging to the order known as *Percomorphi* differ from others in possessing, almost without exception, phenomenal concentrations of vitamins A and D. Thus we find liver oils which contain 50, 100, 500, and even 1,000 times as much vitamin A or vitamin D as average cod liver oil!

Percomorph liver oils are seldom equally rich in both vitamins. By skilful blending of the A-rich oils with the D-rich oils, a mixture is obtained which is about 200 times richer than cod liver oil in both vitamins A and D. As this concentration is so great that an ordinary dose of the oil could not be conveniently measured, we dilute the percomorph oil with approximately one volume of refined cod liver oil.

The resultant product is Mead's Oleum Percomorphum, 50%, which is 100 times cod liver oil* in both vitamins A and D. By a further dilution we obtain Mead's Cod Liver Oil Fortified With Percomorph Liver Oil, 10 times as potent as cod liver oil* in both vitamins A and D. Their respective potencies are 60,000 vitamin A units, 8,500 vitamin D units; and 6,000 vitamin A units, 850 vitamin D units (U.S.P.) per gram.

Just as Oleum Morrhuae is a mixture of the liver oils of various cod species (cf. U.S.P. XI, 1935, p. 261) so Mead's Oleum Percomorphum is a mixture of the liver oils of various percomorph species.** The significant difference is that the improved product is 100 times as potent* in both vitamins A and D.

Mead's Oleum Percomorphum, 50%, is available in 10-drop capsules; 25 in a box; and in 10 cc. and 50 cc. bottles. Mead's Cod Liver Oil Fortified With Percomorph Liver Oil is available in 3 oz. and 16 oz. bottles.

*U.S.P. XI Minimum Standard.
**Principally Xiphias gladius, Pneumatophorus diego, Thunnus thynnus, Stereolepis gigas, and closely allied species.

MENINGOCOCCUS ANTITOXIN

DEVELOPED IN THE RESFARCH LABORATORIES OF PARKE, DAVIS & CO

"Meningococcus Antitoxin has reduced by approximately 50 per cent the deaths from meningococcic meningitis at Cook County Hospital."

> Journal of the American Medical Association, Volume 104, page 980, March 23, 1935

THE introduction of Meningococcus Antitoxin is a significant contribution to the therapy of contagious diseases. Extensive biological and clinical research has led to the development of this true antitoxin, markedly effective in lowering the mortality in meningococcic meningitis.

Accepted for inclusion in New and Nonofficial Remedies by the Council on Pharmacy and Chemistry of the American Medical Association

A Diagnostic Aid

Normal seminal vesicles. Radiograph following Lipiodol injection. The outline of the vasa deferentia is clearly visualized.

TNTUITION alone does not make a clever diagnostician Instead, the modern physician utilizes every available clinical and laboratory device to arrive at a diagnosis

In the past decade, Lipiodol radio graphy has come to the front as an essential technique in diagnosing certain types of diseases

In the first place, Lipiodol radiography may throu light on conditions otherwise obscure, and makes possible the application of radiol ogy to organs and tussues which or dinarily cannot be visualized, for example, the broncho pulmonary system, the female pelvic viscera, cr the seminal vesicles

In the second place, by means of Lipidol radiography, it is possible to obtain clear cut, brillian and conclusive radiographs in which the pathology is clearly defined and precisely demonstrated

Lipiodol (Lafay) is the original French iodized oil. It represents an organic stable combination of 40° 0 iodine with poppy seed oil.

Lipiodol may be injected into nu merous body t ssues and cavities. It is slowly absorbed and slowly elim inated, it is relatively non roxic and non initiating.

The general practitioner

now treats . . HAY FEVER

Successfully

HAY FEVER, it is estimated, affects at least two per cent. of the white population of this country. This means that five of each 250 patients seen by the General Practitioner in the course of a year suffer from attacks of Hay Fever in the early summer or fall. Four out of five of these distressingly afflicted victims can be given decided relief by means of a standardized series of injections.

Such a series of injections is available when Pollen Antigen *Lederle* is employed.

Treatment sets comprise fifteen graduated doses which simplify the administration of appropriate amounts of the specific Pollen Antigen.

LEDERLE LABORATORIES, INC. 30 ROCKEFELLER PLAZA NEW YORK, N. Y.

Miscibility with bowel content is the prime reason for emulsifying mineral oil. Petrolagar represents the result of our twenty years' study and experience with this one problem. Petrolagar permeates the bowel content, prevents the formation of hard masses and brings about a soft, easily passed stool.

Petrolagar is a mechanical emulsion of pure liquid petrolatum (65% by volume) and agar-agar, accepted by the Council on Pharmacy and Chemistry of The American Medical Association for the treatment of constipation.

New York City Eating Less?

The great metropolitan city's consumption of fruits and vegetables has dropped almost 30,-000 car-loads in three years (approximately twenty-five per cent). The greatest proportionate reduction seems to be in sweet potatoes. Only tangerines of some nineteen commodities, showed an increase.

This may be an indication of increased use of canned products (the above is based on fresh products) and perhaps a greater con-

fidence by the public in the improvement that has been made in both quality and taste of canned goods by canning companies. However there is still a vast difference in grades and brands of preserved foods which demands discriminating selection.

Poor home cooking and storage of fresh products remains a handicap to those prescribing diets, which is no doubt a good reason to recommend the use of canned products and their better brands.

CANNED FOODS AND THE PUBLIC HEALTH

II. Iron and Tin Salts

• The question is sometimes raised as to whether the metallic salts which canned foods may acquire from contact with tin containers are objectionable from the stand point of public health We are glad to pre sent the facts in answer to this question

The modern "sanitary style" can is man ufactured from 'tin plate' As the name implies tin plate is made by plating or coating thin steel sheets with pure tin This tin coating cannot be made absolutely continuous, under the microscope, minute areas can be noted in which the steel base is exposed

Foods packed in plain or unenameled cans are, therefore, exposed to iron and time surfaces in enameled cans, foods are mainly in contact with inert lacquers baked onto the tin plate at high temperatures. However, because of minute abrasions in the enamel covering, unavoidably introduced during fabrication of the can, foods in enameled cans may also have limited contacts with iron and tin surfaces.

It is common knowledge that canned foods may acquire small amounts of these metals from contact with their containers. The acquisition of iron and tin salts in this manner is an electrochemical phenomenon (1), and the amounts of these metallic salts thus acquired will depend, among other factors, upon the character of the food In general, the acid foods tend to take

up more of these metals, especially when air is admitted after the can is opened However, the quantities of tin or iron present in canned foods, as a result of reaction with the container, are small, the analytical chemist reports these amounts in 'parts per million'

As far as iron is concerned, it is commonly accepted that the amounts of this element—recognized as essential in human nutrition—which may be present in canned foods, are innocuous

As to the tin salts which may be present in canned foods, the Department of Agri culture has authorized the following state ment as the result of its own investigation

"Our own experimental work, involving the ingestion of far larger amounts of tin than any previously reported, and supported by the experimental evidence of other investigators, leads us to the conclusion that tin, in the amounts ordinarily found in canned foods and in the quantity which would be ingested in the ordinary individual diet, is for all practical purposes, eliminated and is not productive of harmful effects to the consumer of canned foods" (2)

It may therefore be stated that the amounts of tin and iron salts normally present in commercially canned foods are without significance as far as possible haz ard to consumer health is concerned

THE NEW YORK POLYCLINIC

Medical School and Hospital

(ORGANIZED 1881)

(The Pioneer Post-Graduate Medical Institution in America)

OBSTETRICS and GYNECOLOGY

A full time course. In Obstetrics: Lectures; prenatal clinics; witnessing normal and operative deliveries; operative obstetrics (manikin). In Gynecology: Lectures; touch clinics; witnessing operations; examination of patients pre-operatively; follow-up in wards post-operatively. Obstetrical and Gynecological pathology; regional anesthesia (cadaver). Attendance at conferences in Obstetrics and Gynecology. Operative Gynecology on the Cadaver.

For the GENERAL SURGEON

A combined surgical course comprising General Surgery, Traumatic Surgery, Abdominal Surgery, Gastro-Enterology, Proctology, Gynecological Surgery, Urological Surgery, Thoracic Surgery, Pathology, Roentgenology, Physical Therapy, Operative Surgery and Operative Gynecology on the Cadaver.

The Diabetic Over Fifty

Coronary sclerosis is prevalent among older diabetic patients and it has been suggested that all diabetics over fifty years of age be treated as potential heart cases. Since an adequate blood-sugar level may be essential to cardiac nutrition, when Insulin is given in such cases there should be ample "coverage" with carbohydrate.

Iletin (Insulin, Lilly), the first Insulin commercially available in the United States, is supplied through the drug trade in 5-cc. and 10-cc. vials.

TREATMENT OF CANCER PATIENTS

Study of End Results in 351 Autopsied Cases

IRA I. KAPLAN, B.Sc., M.D., New York City
Director Division of Cancer and Director of New York City Cancer Institute,
Department of Hospitals, New York City

At the Cancer Hospital of the New York City Cancer Institute, which constitutes a large important unit of the Division of Cancer of the Department of Hospitals of New York City, we have had the unique opportunity, during the past five years, of caring for and observing several thousand cancer cases (4705), many of whom before coming to us had been treated by almost every method of surgery and irradiation.

A careful study of a large number of these cases including those upon whom autopsies were secured provides an excellent source of information regarding the diagnosis, results of treatment, course of the disease and end results which cannot but lead to a more comprehensive understanding of cancer, help to indicate what errors in diagnosis and therapy are to be avoided, and help to explain some of the untoward conditions occasionally occurring in such cases. The majority of these cases, because of the advanced stage of the disease, survived only a short time after admission to the Cancer Hospital so that intensive treatment of any kind was, of course, out of the question. In 1933 we reported on our study of over 1,000 unselected cases treated at the Cancer Hospital describing the type of cases received

This present study of a group of autopsied cases has served to disclose the fallacy of some widely-held notions regarding modes of extension of the disease, and has clearly demonstrated the lack of uniformity in metastatic invasion.

This paper gives a detailed analysis of statistics obtained from the 351 autopsied cases at the New York City Cancer Hospital during the period 1929–1934. Of these 279 were white patients and seventy-two colored, this being the proportion expected, as colored patients are about one-third the number of the whites in the city population.

Association of syphilis with cancer was rarely noted. Positive findings of this occurred only in forty-two cases. In dealing with cancer we have learned, by experience, that there are certain groups of common occurrences associated with various types of primary malignant lesions, but this autopsy study has shown us that cancer is entirely irregular in its actions and may involve any and all tissues in a most unusual manner.

Not unexpectedly the errors in technic whether of surgery or irradiation, were soon disclosed at autopsy. In many instances it was evident that by simple surgical or medical methods there might have been favorably effected relief of conditions occasioned by mechanical or functional interference with normal physiological body conditions.

During the period 1929-1934 when the Cancer Hospital constituted an integral part of the Cancer Division of the Department of Hospitals, 4705 patients were accepted for care and treatment. These

^{*}Kaplan, Ira I.: Radiology, Volume 20, June 1933.

patients were received in all stages of the cancerous process, regardless of treatment previously administered elsewhere. Many of these cases were in such an advanced stage of the disease when admitted, that it was only possible in most instances, to mitigate the misery of their passing away. During the period under study 2564 cases passed away at the Cancer Hospital. Mostly these patients were placed on custodial care, which means that symptomatic medical and surgical treatment was needed as the exigencies of the case required: i.e., sedatives for pain, hyperdermoclysis and intravenous injections for nourishment, emergency tracheotomies, gastrostomies or colostomies, transfusions, and hygienic measures depending upon the area affected.

During the years comprising this period, many new so-called "advanced methods"

or irradiation therapy were being employed in various cancer centers throughout the city and a large number of patients, so treated were sent to us following adverse reactions or for custodial care because they failed to respond to the treatment administered.

Due to legal restrictions we were not permitted to autopsy all of the patients who died while in our care. We were, however, in a favorable position to evaluate the results of all types of therapeutic measures in current use by observing the end results in patients cared for at the Cancer Hospital or elsewhere and ascertaining at autopsy the true state of affairs with regard to the malignant lesions in many of those who died.

In the autopsied group under discussion, the cases presented malignancies as can be seen in Table I.

Final Causes of Death

In all groups except the cervix, pneumonia was most frequently the cause of death, accounting for 150. (Table II.) In ninety-eight instances inanition (cachexia) was the distinguishing cause and especially was this the case in stomach cancer, where in twenty-one instances death could be definitely ascribed to this cause.

In carcinoma of the cervix we found inanition or cachexia the most common cause of death, fifteen cases; pneumonia

was the principal cause in eleven instances, and nephritis and uremia present in only five cases

In the rectal group, cachexia, twelve, and pneumonia thirteen, were the main causes of death.

Skin Cases Autopsy in thirteen cases of skin malignancy disclosed the error of con sidering this type of lesion innocuous these cases were over forty years of age The face was involved in ten instances, in eight cases the lesion was basal cell, in one case rhabdomyoma, in four cases squamous cell, while bone destruction was evident in two cases Experience showed that in most instances skin malignancy, when not radically and intensively treated, becomes markedly destructive in character and uncontrolled by any means at our com-mand Early surgical removal of rodent ulcers might have prevented extensive tissue destruction

Radium and x-ray therapy were of little avail in six of these cases, the malignancy proceeding despite treatment. Toxic pneumonit was the cause of death in most in-

stances (Table III)

to the floor of the mouth appeared in five Active treatment with x-ray and radium was attempted in five cases with but little result. The endotherm was employed in one case to remove necrotic malignant tissue and involved bone Dissection of neck nodes was not performed in any case, these being treated by intensive x-ray therapy, except in one case where a radium pack for 5500 milligram hours was ad ministered to both sides of the neck our opinion extensive malignancy of the tongue with associated infection mitigates against successful control of the condition by irradiation In eight cases death occurred in less than three months cases lived a year after irradiation treatment and mouth hygiene (Table V)

Plarynx The pharynx was the seat of primary mulignancy in five cases, in four cases the lesion was epithelionin, in one lymphosarcoma. One case treated by x ray therapy lived two years under treatment and in one case where the uvula was involved, x-ray and radium prolonged life for three years. Irradiation therapy given in time is a treatment of real worth in this type of malignancy. (Table VI)

Larynx The nine cases of larynx carci noma included three extrinsic, three intrinsic types, one primary involvement of the epi glottis and in two cases the original lesion could not be visualized. All cases had neck node involvement and the Wassermann was negative in every case Tracheotomy was imperative in seven cases and in two gas trostomy had to be performed in order that the patient be nourished. Intensive a ray therapy was employed in five cases, but in no instance was the lesion inhibited. Listulae into the esophagus occurred in three cases, due to malignant extension observations lead us to believe that x ray therapy to be of value must be applied early in the disease. Advanced laryngeal malignancy cannot be controlled even by intensive irradiation (Table VII)

Tonsil It is interesting to note that all five cases of tonsillar malignancy occurred in persons over fifty-five years of age and all were white males In four cases neck nodes were noticeable. In only one case was active irradiation therapy attempted At autopsy, metristasis was found in the lungs in two cases the spleen in one, and the skeleton in one. (Table VIII)

Antrum A study of the three antrum cases proved that these are quite rapidly fatal, following surgical treatment alone To be effective, treatment of this condition must be ridical and a combination of surgery and irradiation. Bone invasion and destruction are common in this type tumor

A review of the cases in the oral groups disclosed the fact that syphilis was a dominant finding only in longue cases where it constituted an incidence of forty one percent. It was noted too that distant metases were associated with tongue, pharying, and tonsit malignancy, whereas the mouth and larying produced only local metastatic manifestations. (Table IX.)

Thymic There were four cases of thymic tumors and all were in patients over thirtyfive years of age. In only one instance was the clinical diagnosis correct and this was based on biopsy finding of a neck node. In the other three cases the diagnosis was made of lymphosarcoma carcinoma of the esoplingus, and carcinoma of lung one case, because of difficulty in swillowing and the diagnosis of esophageal cancer, a Irradiation gastrostomy was performed was employed in all cases but only tem porary response by the tumor followed in our opinion permanent destruction of the tumor by irradiation is not possible In three cases autopsy revealed early and extensive invasion of the pericardium and lungs, another factor precluding successful control by irradiation (Table X)

Lung There were ten cases of lung malignancy and as to be expected all were males, and in only eight cases was the clinical diagnosis correct before death five cases the tumor involved the right side and in two cases supraclavicular nodes were palpable Pain and coughing were the most prominent symptoms displayed by the patients. In eight instances the autopsies revealed the site of the malignant lesson to be in the bronchus X ray therapy was ad ministered in three instances, but with little In most instances custodial care was all that could be given Bone metas tases was found only in one case In five cases the opposite lung was the sent of the metastases the liver was involved in two instances, the kidney was invaded in only one, and the adrenals were involved in three cases One case particula ly was of interest having lived four years-two at the Cancer Hospital under custodial care only (Table XI)

Bone Bone tumors were little effected by irradiation treatment and death in most in stances from associated pneumonia followed In our opinion early radical surgery is the treatment of choice whenever it is possible of performance (Table XII)

Esophagus There were twenty cases of esophagus cancer autopsied A most striking observation was that practically all of these patients were extremely emaciated their skin parchment like—extremely dry, and stretched over the skeleton in such a

manner as to reveal its whole structure. Fourteen of these cases died in less than two months after admission. gastrostomy was necessary in seven cases with fatal results in all within a few days Autopsy indicated that of the operation. in most cases the malignancy had existed for a long time and that delay in seeking early relief was the cause of the rapidly hastening fatal outcome after the patients reached the hospital. In advanced cases irradiation is of little avail in inhibiting the

malignancy and may even hasten death. (Table XIII.)

A study of the thirty-nine Stomach: cases of malignancy of the stomach revealed some interesting facts. portion of white patients was almost twice that of colored; males exceeded females. condition occurred approximately equally in all decades from thirty-three to seventy-nine years of age, but it is surprising to find seven cases between the thirtythree and thirty-eight age group constituting sixteen per cent of all stomach cases. In thirty-five cases the clinical diagnosis was made from the important and constant symptoms of pain and vomiting; in twentyseven the roentgenographic examination was positive, and in three cases the wrong diagnosis was made. Because of the advanced condition that these cases presented, only custodial care could be given In but three instances was irradiation in the form of x-ray therapy attempted, and then only as a palliative. Judging from our observations in these thirty-nine cases, irradiation offers no help in advanced cancer of the stomach conditions nor are surgical procedures of real value except in the very early cases. (Table XIV.)

Treatment at Cancer Hospital: Surgery Jejunostomy 1; Irradiation X-ray 3; Custedial 35.

Duration of life-All cases: Less than 1 month 17; 1 to 3 months 19; 6 months to 1 year 2; Over 1 year 1.

Duration of life—Untreated cases: 25 Cases (Less than 1 month 11; 1 to 3 months 12; 3 months to 1 year 2.)

Cause of death: Inanition 21; Peritonitis 2; Pneu nonia 15; Hemorrhage 1; Autopsy: Positive 39.

Pathology of lesions found: Adeno Ca. 33; Small cell 1; Gelatinous ca. 2; Krukenberg 1; Sarcoma 1; Ca. 1.

Metastasci: Generalized 1: (Breast, Liver, Omentum, Nodes : Lung 2; Pleura 1; Ovary ; Diaphragm 1; Skin 1; Spleen 1; Inguinal Nodes 1; Krukenberg 1; Case double primary ca. stomach with sa. abdominal tumor 1.

Liver Because of infrequent occurrence, positive diagnosis in primary liver miliginancies is seldom correctly mide before operations. In our series of eight cases considered miliginant only three had the diagnosis confirmed by operation, and autopsyproved only four to be miliginant. X-ray diagnosis was shown completely in error three mistances. The two cases that hied over one year corroborated again the customary assumption that patients remaining long alive without radical treatment are probably not malignant even though exhibiting all the seeminely positive clinical signs of milignancy. (Table XV.)

Pancreas In only one of the eight cases of autopsy proven malignancy of the pancreas, was positive diagnosis made before death. All sorts of diagnosis had been made, because the symptoms and clinical signs mostly referred to other organs more commonly affected by malignancy No patient lived beyond three months after admission to the hospital thus showing the rapidity with which this type of lesion progresses In seven cases custodial care only was possible, in two cases, because of the supposition they were Hodgkin's irradiation was Autopsy showed eight cases of attempted this series to be carcinoma of the pancreas. in one case a purulent abscess of the pancreas was found without definite evidence of malignancy (Table XVI)

Gall bladder None of the three cases of gall bladder disease autopsted was correctly diagnosed before death, in each instance carcinoma of the panerers was suggested. Autopsy proved only one case to be cancer of the gall bladder. The other two were benign conditions. The patients

was the progress of the disease arrested. In twelve cases death was directly due to the malignant cachexia and in thirteen cases terminal pneumonia was the cause of death. (Table XVIII.)

Breast: In this group there were thirtyeight cases involving thirty-seven females and one male. Of these, twenty-one females and one male were treated by radical surgery before admittance to the Cancer Hospital. In our study of the cases of breast cancer we find that radical breast surgery alone is not the method offering the best opportunity for curing this condition, for in the thirtyeight cases autopsied, generalized skeletal metastases occurred most frequently in the cases which had been operated upon in that manner: fourteen of the twenty-two cases, treated by radical surgery alone, exhibited bone metastases, while only seven cases of the seventeen not treated by surgery showed this complication. In no instance did these operated cases have postoperative x-ray therapy. In our series only two cases had irradiation with surgery and two cases irradiation alone as the treatment before entering the Cancer Hospital. opinion, based on the study of living cases, preoperative and postoperative x-ray therapy does actually prevent or inhibit bone metastasis. Preoperative x-ray therapy was in no instance employed. In this series the

removal of the involved breast possible Palliative irradiation was employed in fifteen cases. In three bed-ridden cases radium was used in the form of a pack over bone In no instance was the disease cured or more than temporarily retarded (Table XIX)

There were four cases of vulva Vulvamalignancy, three of whom gave positive evidence of previous luetic infection. All four patients had borne children, two of the All patients were white and two colored four cases were of the squamous cell epithelioma type. In one case metastases was found in the pelvic bone (Table XX.)

The thirty-six cases autopsied disclosed some enlightening data white patients were almost twice as many as the colored This type lesion occurred most often in married women of the fourth

to fifth decade of life

Notwithstanding the admitted superiority of irradiation over surgical procedures for cancer of the cervix, quite a number of patients are still being treated by hysterectomy Our observations lead us to beheve, moreover, that cervix cancer remains localized for a long period of time and extension is local in most instances twenty-nine instances the adnexa were involved, in ninetcen a "frozen" pelvis condition existed

In our findings, fistulae occurred most often from two conditions, in cases where the technic of treatment was faulty, and in advanced cases from ulceration and

Duration from onset of illness: 0 to 1 years 11; 1 to 2 years, 7; 2 to 3 years, 4; X-ray had no effect. Early fatal cases also had x-ray.

malignant extension. This latter, however, was a very late occurrence and less frequently found than that associated with faulty irradiation technic. Metastases were not common in the cases studied and occasional appearances were rather unusual in occurrence.

There were six cases or sixteen per cent with liver involvement. In no instance were we able to find evidence of irradiation destruction of the ureters, but in twenty-three cases ureteral obstruction was found, twelve unilateral and eleven bilateral. It should be emphasized, however, that in every case this obstruction was due to malignant extension to the pelvic nodes with malignant lymph-node encroachment on the ureters with subsequent tube block. In spite of the finding of bilateral ureteral blockage at autopsy in eleven cases, only two cases were reported as having died from uremia.

In four instances of severe pelvic and thigh pain nerve block was attempted, but in no case was permanent relief secured by

this procedure.

In only one instance did pelvic extension of the malignant process require colostomy for relief of lower intestinal obstruction. Although irradiation controlled the bleeding in all instances, in none of the cases did it control the destructive process of the disease. Reviewing the modes of treatment administered to the patients before they entered the Cancer Hospital, we are of the conclusion that active treatment, to be of value, must be properly applied and effected when employed, otherwise the condition first Secondary progressively becomes worse. treatments, whatever their nature, are of little avail in arresting the cancer process. Death in cervix cancer occurred in most instances from malignant inanition cachexia and in only five cases was nephritis or uremia the cause; terminal pneumonia occurred in eleven cases, and peritonitis in five. (Table XXI.)

Uterus: Six cases of malignancy of the uterus were autopsied. In four the diagnosis was correct; in two cases cancer of the cervix was erroneously made because the principal findings showed involvement of the cervix. In one case sarcoma was the pathological finding and in four the adnexa Bleeding was the most was involved. prominent symptom exhibited by all cases. In only one was a previous hysterectomy performed. Active treatment at the Cancer Hospital was possible in only two cases, x-ray and radium being employed.

The sarcoma case was unusual in as much as it arose seemingly on a previous fibroid development in the uterus; in this case metastates were found in the lung, pleura, liver, mesentery, ovary, ribs, long bones,

Because this case was so adand skull vanced, only custodial care could be given The diffuse metastates suggested that we were not treating the usual cancer of the uterus (Table XXII)

A study of the eighteen cases of ovarian malignancy showed their number to be almost equal in all decades, the smallest number occurring in the fourth and fifth decades Abdominal swelling was the most prominent symptom in most in stances and diagnosis was not difficult

In spite of all treatments, death occurred after admission three months Extension and metastasis were rapid and widespread, the liver and peritoneum being most often involved. In our opinion, early radical extirpation of the malignant tissues in the abdomen, followed by intensive x-ray therapy, is the only treatment of value, and any other measures are of little avail in arresting the progress of this disease (Table XXIII)

Prostate In the twenty two prostate cases, lues was concomitant in only one instance The usual history indicated occurrence of the cancer for years before death and, therefore, in our experience this disease is one of slow progress Surgical procedures exclusively were employed in this disease and in only two cases had irradiation been employed Bone metastasis occurs in late cases rather frequently, twelve were so involved. It was noted too, that diffuse generalized visceral metastases were frequently found, contrary to our previous ideas in this matter At the Cancer Hospital, x ray therapy was used in all instances for palliation alone, since it was of little value in arresting the progress of the disease Terminal pneumonia was the most common anatomical cause of death (Table XXIV)

Testicle There was only one case au topsied and this proved to be one of chorio epithelioma The course of the disease was very rapid and treatment was only pallirtive (Table XXV)

Bladder In only three of the eight cases of bladder malignancy was hematuria a noticeable symptom before death and in only one instance was the Wassermann posi-In seven cases the disease was so advanced that only custodial care could be given Five cases had a suprapubic opera-Metastases were uncommon (Table tion XXVI)

Kidnev Only three cases of kidney malignancy came to autopsy In two cases a correct diagnosis was made during life In two cases, the extensions were first discovered, in the vagina in one biopsy proving hypernephroma, in one a supraclavicular

TABLE XXVIII. SOFT TISSUE SARCOMA

Color: White 3. (All Male.)

Marital state: Married 1; Single 2.

Birthplace: U. S. A. 2; Foreign 1.

Religion: Catholic 2; Protestant 1. Ages: 40 years 1; 48 years 1; 61 years 1. Symptoms: All complained of pain and mass. Local conditions involved: Left thigh 1; Buttock 2. Physical examination: Nodes 2 cases; 1 case of buttock sa. had axillary metastases. Previous operation: Removed surgically 3; (All within 1 year.) Treatment at Cancer Hospital: X-ray 3. Duration of life after admittance to Cancer Hospital: Less than 1 year 2; 2 years 1; (neurogenic). Cause of death: Pneumonia 2; Inanition 1. Autopsy findings: Spindle cell 1; Neurogenic sa. 1; Myxo, sa. 1.

TABLE XXIX, MALIGNANT CASE

Cerebellar Tumor: White, male, 12 years old, single. born U. S. A. Symptoms: Headache, nausca, vomiting, unsteady gait, blindness, protruding mass from skull.

Wassermann: 2-Plus.

Treatment: Spinal tap; decompression of skull; antileutic.

Cause of death: Coma.

Duration of disease: 1 year. Duration at hospital: 3 months.

Autopsy: Cerebellar tumor; medublastoma.

Other findings: Pulmonary metastases 2.

TABLE XXX. MALIGNANT CASE

Branchiogenic Ca. of Neck: White, male, 50 years old, married, foreign.

Symptoms: Swelling and pain in neck, cough. Physical examination: Large, ulcerated neck tumor.

Biopsy: Branchiogenic carcinoma.

X-ray examination: Suggested tbc. Treatment: Custodial care.

Cause of death: Meningitis.

Duration of disease: 11/2 years.

Duration at Hospital: 1 month.

Autopsy: Branchiogenic Ca. with metastasis to neck, tracheobroncheal lymph nodes, and liver; Serous meningitis and chronic pulmonary tbc.

TABLE XXXI. MALIGNANT CASE

Choroid Melanoma-Right Eye: White, male, 32 years old, married, born U. S. A. Symptoms: Ataxia, tumor of right eye, pain in limbs. Previous treatment: Enucleation rt. eye (6 months.) Previous examination: Orbital tumor, very large nodular liver. X-ray examination: Shows destructive skeletal metastasis. Treatment: X-ray therapy. Duration of disease: 6 months.

Duration at hospital: 1 month.

Autopsy: Melanoma of choroid right eye.

Metastasis to: Liver, lung, pancreas, bones and nodes.

Leukemias, Hodgkin's disease, and lympho-These conditions were only sarcoma: temporarily controlled by irradiation. Soft tissue sarcomas were little affected by any form of therapy. Death ensued either from pneumonia or inanition. (Table XXVIII).

TABLE XXXII. MALIGNANT CASE

Generalized Carcinomatosis: White, male, 55 years old, married, foreign.

Symptoms: Pain throughout body, stiff neck, loss of weight.

Physical examination: Numerous small skin nodules; Large abdominal mass; Nodes in neck.

X-ray examination: Destructive metastasis throughout skeleton.

Biopsy: Neck nodes; Adeno. ca.

Treatment: X-ray therapy.

Cause of death: Inanition; Cachexia; Pneumonia.

Duration of disease: 9 months.

Duration at hospital: 1 month.

Autopsy: Generalized carcinomatosis; lobar pneumonia.

TABLE XXXIII. LEUKEMIA

Color: White 3.

Marital state: Married 2; Single 1.

Birthplace: U. S. A. 2; Foreign 1.

Religion: Catholic 2; Protestant 1.

Age: 49 years 1; 57 years 1; 67 years 1.

Sex: Male 2; Female 1

Symptoms: Weakness 3; Abdominal pain 2; Masses, nodes 1 (lymph).

Physical examination: Lymphatic—all nodes plus very large spleen Myelogenous—Spleen 2 (large); Liver

Clinical diagnosis: All correct.

X-ray diagnosis: Lymphatic had pleural effusion.

Wassermann: All negative.

Treatment at Cancer Hospital: X-ray 2; Custodial 1. Duration of life after admittance to Cancer Hospital: Lymphatic: 6 months. Myclogenous: 4 months 1 case; 1 year 1 case.

Cause of death: Pneumonia 1; Inanition 2.

Autopsy findings: Lymphatic: Spleen and all nodes.
Myclogenous: 1 case had leukemia areas in liver,
kidneys, and sternum.

patients at death Because of the metastatic character of the lesions present and the histological findings of these tumors, we are not ready to characterize these lesions other than as secondary malignancies with the primary focus undetermined (Table XXXVI).

Nonmalignant Because the Cancer Hospital is a free Municipal Institution, whose beds are always available for the reception of cancer patients from any hospital in the city without delay or undue questioning from time to time there are transferred to the patients in whom after careful examination no evidence of malignancy can be found There were seven such cases In three cases malignancy was suspected and in all cases diagnosed clinically, though autopsy proved them to be of the nonmalignant group (Table XXXVII).

Conclusions

Malignancy, in any location, is controlled only when recognized and diagnosed early and when complete adequate and intensive treatment is carried out at once. Irradiation is effective in controlling malignancy in its early stages and is a worth-while palliative measure only in a number of advanced cases

Irradiation is of little benefit in the treatment of advanced malignancy. Bone malignancy was little affected by irradiation therapy, nor was cancer of the lung responsive to this form of therapy.

In cases of advanced malignancy much can be done by judicious employment of surgery and irradiation to ameliorate acute urgent disturbances of physiological body functions and as a palliative measure to reduce the severity of pain associated with cancer. Surgical removal of obnoxious and decayed tissue may often prolong life free from misery though the primary malignant lesion progress and ultimately cause death

Malignancy may metastasize anywhere and the primary lesion is not always limited to the area visible or palpable. Irradiation treatment for cancer must cover the whole body and those areas most likely to become involved by extension and metastasis.

My thanks are herewith tendered to my staff of the New York City Cancer Institute who materially aided in the preparation of the data for this paper.

55 East 86th Street

Discussion

DR. ANGELO M. SALA, New York City-Dr. Kaplan has clearly summarized for us the lessons of the autopsy table. His task has been necessarily concerned with the seamy side of the cancer picture for in the hospital of the New York City Cancer Institute we usually get what is left by others and often it is not much. I know that there is another, a fairly cheerful side to the picture; that there are cures of malignant disease. Yet, if we are to enhance our diagnostic acumen and thereapeutic skill, we must pause now and again to look back at the mistakes that lie buried in countless graves. It is here that the pathologist who is interested in cancer (please note that I refuse to employ the term "cancer pathologist") comes into the sphere of his greatest usefulness, and becomes again what he should never have ceased to have been, a doctor and an adviser to his colleagues.

As I think back on the silent teachers of the autopsy table, certain indelible impressions come to the fore. One of them is that a certain percentage of errors in diagnosis will ever be with us; but I must say that if doctors thought more and more that there is such a disease as cancer, using the word in its broadest sense, and suspected it more often, this percentage would soon be reduced to an irreducible minimum. Lumps in breasts are still treated with salves by physicians, cervical node enlargements are still subjected to alpine light treatments without the benefit of even a blood count, glycerine tampons are still applied to early carcinomas of the cervix, and hemorrhoids are still treated as such with not even a digital rectal examination.

The presence of a positive Wassermann reaction still leads to prolonged antileutic treatment of lesions that are carcinomatous from the beginning. Unless we drive continuously at the fact that cancer is with us and will be with us in increasing numbers as more people live to adult life—for this very reason we must look for cancer as we do for other conditions—the tragedy of an unjustifiably large percentage of diagnostic errors is bound to be permanent.

Where the diagnosis has been made correctly and reasonably early, there are other lessons to be learned at the autopsy table. One of them is that certain neoplastic conditions are at present hopeless from the start and run a definite course with or without therapy of any sort. Another one is that the diagnosis of malignant neoplastic disease brings about in some physicians a distinctly defeatist attitude. I have had occasions to point out to our staff on the basis of autopsy findings, dove-tailed with the clinical history,

a reasonable certainty on my part that courageous surgery might have saved some cases of gastric carcinoma that have come Some carto postmortem examination. cinomata of the large intestine also should have had a more daring approach than a simple colostomy. I am also impressed with the fact that the treatment of cervical cancer leaves in many instances much to be desired. Therapy that clears up the local lesion and allows the metastases to go merrily on is plainly insufficient. On the other hand the type of therapy that destroys malignant tissue and at the same time brings on huge vesicovaginal and rectovaginal fistulae with death ultimately by sepsis is plainly too much. There are still people using radium who know neither its limitations nor its destructive potentialities.

The question of metastases from the standpoint both of location and time of appearance must be considered. In a general way it is true that the sites of metastases from a given primary malignant neoplasm can be predicted in a fairly accurate manner. And yet our experience is daily pointing out that metastases do occur outside of the beaten paths. It is in fact our distinct impression that they are going to be more and more common. As we enable cancer patients to live longer, automatically we give metastases more time to develop. On this basis, the criterion of the "five year cure" will soon have to be revised; perhaps we had better stop speaking of "cures" and call them "arrested cases" much as we do in phthisis. Certainly a patient is not cured of her breast carcinoma when rib and ovarian metastases are found nine years after the radical mastectomy. We have had such cases. Again in the light of our autopsy experience, we are not going to stop at the pelvis when looking for extensions of cervical carcinoma, because we have found them as high as the hilus nodes and the lungs; nor are we going to stop at the neck when looking for extensions of tongue and pharyngeal carcinoma because we have found them in ribs and heart muscle. I positively refuse to say that such and such a type of cancer will never do this or that, because every time I have made such a statement, my next autopsy is wrong.

There is nothing that a malignant neoplasm cannot and will not do if given time and opportunity. With this thought forever uppermost in his mind the cautious physician, when dealing with cancer, will forever be on his guard because being in the usual case handicapped from the start, inattention will often make victory on his part utterly unattainable.

VACCINE THERAPY IN CHRONIC ARTHRITIS

JOSEPH KOVACS, M.D., New York City From the Arthritis Clinic of St. Luke's Hospital, New York City

In recent years a great deal of attention has been given to the effect of vaccine therapy in chronic nonspecific arthritis. Innumerable workers have reported, with considerable diversity of opinion, the results of their investigations. The purpose of this article is to consider the merits of vaccine therapy in chronic arthritis and therefore present to the practitioner, first, summaries and discussions of the different methods of vaccine therapy; second, clinical and laboratory evidence for and against the different vaccines; third, therapeutic results of vaccine therapy as reported; and finally my own impression of the relative value of vaccine therapy.

It is impossible to include here abstracts of the voluminous and often contradictory literature on this subject; I have summarized only the papers that appear

to be the most significant.

Vaccine therapy is based on the assumption that nonspecific chronic arthritis appears to be due to an infection of bacteria of low virulence. So far there is no general agreement regarding a specific bacterium, since no organism has been isolated consistently by any of the observers who have cultured blood, synovial fluid, joint tissues, and subcutaneous nodules. In recent years, however, experimental work of most observers in the United States,1-8 has pointed to the streptococcus as the organism most frequently isolated in chronic rheumatoid, so-called "atrophic" or "infectious" arthritis. Their findings are today generally accepted, and the rheumatoid type of chronic arthritis is looked on as due to an infection by streptococci of low virulence. On the other hand, Crowe and his school in England are convinced that osteoarthritis, also called hypertrophic or degenerative arthritis, is the result of a streptococcus infection, whereas in most cases of rheumatoid arthritis, we have to deal primarily with a staphylococcus infection, especially with the so-called micrococcus deformans, and that streptococci involved are only secondary invaders. Burbank10 and his followers are

inclined to accept bacterial infection as the etiological factor in both types of arthritis.

This very decided difference of opinion demonstrates the lack of definite proof that a single specific organism causes chronic arthritis. Nevertheless, the generally accepted existence of bacterial infection has served as a justification of the use of vaccine therapy.

Methods of Vaccine Therapy

Vaccine therapy is employed either by the subcutaneous or by the intravenous method. Notwithstanding the fact that the two methods are based on quite different theories, their therapeutic object is identical, the endeavor to overcome the assumed bacterial infection.

Subcutaneous administration: Subcutaneous vaccine therapy is based on the assumption that vaccine as an antigen stimulates the production of antibodies and increases the immune reaction of the body against infection. The antigenic activity of the vaccine is primarily associated with proteins, probably with their aromatic radicals, but certain lipoids and carbohydrates appear also to figure in the reaction. Subcutaneous vaccine treatment gives rise to humoral and cellular insmunity; that is, the cells of the tissues are stimulated, and the products of that reaction are set free in the body fluids. Subcutaneous vaccine therapy has been used extensively and exclusively for many years in the treatment of arthritis, and there are still enthusiastic advocates of this method.

Intravenous administration: The recent theory of Swift,11-12 Klinge,13 and Zinsser14 that allergy constitutes the most important background for the development of chronic arthritis, brought forth the intravenous administration of vaccines. These workers believe that the pathological changes in chronic arthritis, although they may be caused by bacterial infection, are not the direct result of the action of specific bacterial toxins, but arise from a sensitization to the bacterial protein. The experimental works Swift18-18 and Clawson19 in rheumatic

fever and chronic arthritis suggested that subcutaneous vaccination, instead of desensitizing the hypersensitive arthritic individual, tends to increase his hypersensitiveness, while, on the other hand, repeated small doses of vaccine administered intravenously at proper intervals desensitize the patient and produce a higher degree of protective immunity. As a result of these findings subcutaneous injection was abandoned by most men, and vaccine is now being administered intravenously far more widely.

Types of Vaccines

The vaccines used in chronic arthritis are of two general types: autogenous vaccines and stock vaccines. In discussing their relative merits special attention must be given to the different commercial vaccine products in order to make it clear to the practitioner what he may expect from such vaccines.

Autogenous vaccine: Following the assumption that vaccine to be efficient must be as specific as possible, many investigators believe that autogenous vaccine is the only effective form of vaccine therapy. Cultures are taken from throat, tonsils, sinuses, nasopharynx, abscessed and devitalized teeth, synovial fluid, duodenal content, stool, intestinal wall, urine, prostatic secretion, neck of the uterus, and other possible sources. From the autogenous culture the assumed pathological strains are isolated and a heat or phenolkilled vaccine is prepared from them. Theoretically, autogenous vaccine therapy is very promising, but it does not prove to be so successful in practice.

The different methods which have been recommended for the selection of specific vaccine strains, as complement fixation, agglutination, and skin test, are based on theories without definite proof and cannot be accepted without reservation. Such positive tests cannot be considered as conclusive evidence that the infecting agent causing the arthritis has been found. There are many other complicating factors which may be responsible for the positive test.

No proof has been furnished that the cultured strains are really responsible for the arthritis changes, inasmuch as most of these strains can also be found in perfectly healthy individuals. The fact that

in the cultures of arthritis patients several strains of bacteria are usually found, makes it difficult to believe that the arthritis process is caused simultaneously by several different strains of bacteria.

Burbank²⁰ and his followers, to make the autogenous vaccine still more powerful, mix it with a vaccine prepared from all the fecal strains that gave a positive complement fixation with the serum of the patient.

Crowe²¹ and his followers use a polyvalent mixed type of vaccine consisting of autogenous vaccine and a stock vaccine composed of 156 strains of nonhemolytic streptococci, and also a staphylococcus stock vaccine prepared from the strain of micrococcus deformans.

Autogenous vaccine is generally employed subcutaneously as an immunizing factor; only a few men administer it as a desensitizing agent intravenously.

The usual strength of autogenous vaccine for subcutaneous administration is 10,000 millions in one c.c. The initial dose is usually 0.1 c.c., and if there be no systemic reaction, the dose is increased 0.1 c.c. each time, until the total volume of one c.c. is reached. The dosage seldom exceeds one c.c. If a reaction follows the injection, such as increased pain, chills, temperature, etc., the next dosage should be reduced to half the amount which caused the reaction. For intravenous administration, much smaller doses are used, similar to stock vaccines.

Autogenous vaccine, generally made up from several strains of bacteria, being a mixed vaccine, cannot be as specific as it is assumed to be. In a mixed vaccine of so many strains, as are the vaccines used by Burbank, and Crowe and his followers, there cannot be much specificity, and I agree with Short²² and his coworkers that the effect gained from autogenous vaccines is a nonspecific effect.

Stock vaccine: The finding of Cecil²³ and the work of Small,²⁴ and Clawson and Wetherby²⁵ indicate that there are typical strains of bacteria in chronic arthritis which may be responsible for the disease. This assumption led to the introduction of stock vaccine prepared from these typical strains. Today most clinics in this country use these different stock vaccines. The best known and most widely used stock vaccine is prepared

from Cecil's typical strain of alpha prime streptococcus, labelled Ab 13. There are also many other stock vaccines in use from other strains of streptococcus hemolyticus and streptococcus viridans. Stock vaccines are usually heat-killed vaccines; phenol-killed stock vaccines are rare. Stock vaccines are usually given intravenously for desensitizing purposes. A very small dosage is given at the start, 10.000-50.000 bacteria, increasing gradually, avoiding pronounced constitutional reaction, and especially joint reactions, An injection is given every four or five

important advantage of stock The vaccine is that it greatly simplifies vaccine therapy and eliminates the tiresome culturing of every possible focus for autogenous vaccine. The drawback of a stock vaccine is that -- so far -- we cannot accept any specific exciting cause as an etiological factor in chronic arthritis since no organism has been found consistently by all observers (see above). workers have found not only different bacteria of the same group, but quite different groups of bacteria, all seemingly

responsible for the disease.

This fact alone undermines the theoretical basis of the specificity of stock vaccine treatment. Until more positive findings reveal one specific organism as the etiological factor in arthritis, the stock vaccine therapy of today cannot be looked on as a specific therapy for arthritis.

Commercial vaccines: The different commercial vaccines put on the market by various companies are usually mixed stock vaccines. The vaccines of Lederle and other companies contain several strains of streptococci and staphylococci, and some companies add to it colon bacilli and pneumococci. They are heat-killed or chemically-killed vaccines. There are two vaccines on the market which claim specificity in arthritis. One has been brought out by Lilly and Co. and is made up from a strain of streptococcus viridans or alpha streptococcus isolated by Wetherby and Clawson. These workers claim that the effect of this vaccine is rather a group specific effect. It is used intravenously for desensitization and immunization. The micro-organism was isolated from the blood of a patient with rheumatic fever and pericarditis. It has been under cultivation for nine years. The vaccine is given intravenously. The initial dose recommended is one hundred million (1 c.c.) killed streptococci, and is increased one hundred million (1 c.c.) weekly until eight hundred million (8 c.c.) This large dose, tolerated is reached. without any reaction, arouses some doubt in our minds as to the toxic products of the strain. It may be that the strains cultured for so many years have lost their virulence and have a decreased toxicity and immunizing power, and that therefore the vaccine prepared from them can be tolerated in so large a dose. The claim as to the group specificity of the vaccine is also debatable. Taking into further consideration that there is no proof that strains of streptococcus viridans are really responsible for chronic arthritis, the claimed specificity of the Lilly vaccine

cannot be accepted.

The special arthritis vaccine introduced by Parke, Davis & Co. is called Streptococcus Immunogen (Arthritis). It is claimed to be a superior biological product, providing the maximal amount of antigenic substance with the least possible amount of nonspecific protein. It is based on the theory that immunogens are ectoantigens, derived mainly from the ectoplasm of the bacterial cells. In preparation the live organisms are extracted with physiological salt solution immediately on being taken from the culture medium. The vaccine is standardized so that one c.c. of vaccine contains the antigen of two thousand million organisms. The initial dose is 0.1 c.c. (200 million antigen) intravenously and is increased slowly to three to five c.c. (10,000 million antigen) This vaccine is a mixed vaccine prepared from different strains of streptococcus viridans and hemolyticus. The theory on which the vaccine is prepared is not generally accepted, and the fact that such enormous doses are tolerated without any reaction causes the same doubt as to its efficacy.

Therapeutic Results

The voluminous literature concerning vaccine therapy by different types of vaccines and by different methods of administration, as a rule gives results based on clinical observations only. The evaluation of these claims presents inherent difficulties. The main objections are:
(1) lack of efficient adequate control;
(2) differing interpretations of the varying forms and degree of the disease;
(3) comparatively short time of observation of a long standing chronic disease in which spontaneous improvements and re-

320

tion of a long standing chronic disease in which spontaneous improvements and remissions are common; (4) the fact that in most cases vaccine therapy was combined with other forms of treatment, such as rest, diet, physical therapy, and drugs, making it impossible to obtain a clear-cut picture and decide which form of therapy was most beneficial.

The therapeutic reports can be divided into three groups. The first group claims beneficial results from vaccine therapy in every type of arthritis and believes in its specificity. The second group uses vaccine only in the rheumatoid type of arthritis where infection is generally accepted as the etiological factor. Its members claim to have comparatively better therapeutic results if vaccine therapy is instituted along with other forms of treatment. The third group could not find better results with vaccine therapy than with other usual methods.

Table I gives a summary of these reports. In the first group are found the reports of Burbank and Christensen,²⁶ Crowe,²⁷ and Wetherby-Clawson.²⁸ They use vaccine in every type of chronic nonspecific arthritis and report a general

improvement in 80–92.5% of the cases. Burbank and Crowe admit having employed at the same time other forms of therapy, such as diet, drugs, physical therapy, and removal of various foci of infection.

I do not doubt the sincerity and good faith of these reports, but the comparatively short time of observation, the lack of differentiation of the varying forms and degrees of disease makes them incomplete and inconclusive. It is difficult to explain why other workers, employing the same methods, could not duplicate their results. It is also questionable if vaccine therapy has any justification in both types of arthritis. The majority of the workers look upon osteoarthritis as a degenerative senescent disease in which infection plays no part, and feel that vaccine therapy is out of place in this type of arthritis. This is the conviction of Cecil,29 Gray,30 and Rawls31 whose reports are contained in the second group. They believe that vaccine should be applied only in cases of rheumatoid arthritis. As to therapeutic results, Rawls' paper is the only one which reports general improvement. He claims eighty per cent improvement in cases treated with vaccine, whereas without vaccine the improvement was only twenty-five per cent. The short time of observation (average ten months) and the criteria on which he based the

TABLE I
Therapeutic Results of Vaccine Treatments from Three Groups of Investigators

•			Form of	
Name	Type of arthritis	Type of vaccine	administration	Claimed results
Burbank and Christensen	Osteo and rheumatoid	Autogenous-stock (polyvalent)	Subcutaneous	Improvement in 92.5%
I Crowe	Osteo and rheumatoid	Polyvalent stock — autogenous	Subcutaneous	Improvement in mild cases 82% severe cases 52%
Wetherby and Clawson	Osteo and rheumatoid	Stock (strep. viridans)	Intravenous	Improvement in 80%
Cecil	Rheumatoid	Stock (AB 13)	Intravenous	Noncommittal on results
II Gray	Rheumatoid	Autogenous and stock	Intravenous Subcutaneous	Improvement in cases where other form of treatment failed
Rawls	Rheumatoid	Autogenous	Intravenous	Improvement in 79%
Congdon	Rheumatoid	Polyvalent stock (46 strain of strep, Viridans)	Subcutaneous	No better results than other methods of treatment
Stainsby and Nichols	Rheumatoid	Stock (AB 13) Autogenous	Subcutaneous Intravenous	Improvement in 35.6%
III Archer	Rheumatoid	Stock (AB 13 and Wetherby's strain)	Intravenous	No better results than other methods of treatment
Kinsella	Rheumatoid	Stock	Intravenous Subcutaneous	Not encouraging improve- ments
Dawson and Boots	Rheumatoid	Stock Autogenous	Intravenous Subcutaneous	No better results than other methods of treatment

conclusion of his observation, (the supposed lowering of the sedimentation rate which was not duplicated by other research workers) raise justifiable doubts as to acceptance of his report as conclusive Cecil and Gray are noncommittal regarding a definite percentage of improvement but report better results with vaccine therapy than without it

The third group, containing the papers of Congdon, 3° Stainsby-Nicholls, 3° Archer, 34 Kinsella, 3° and Dawson-Boots, 30° could not detect better results with vaccine therapy than with any other methods of treatment Stainsby-Nicholls' impressive and detailed report showed very disappointing results with every form of vaccine therapy. The low (35.6) percentage of improvement in their series of cases is very near to the natural tendency of improvement regardless of treatment.

During the last four years I have had the opportunity to observe the therapeutic results of vaccine therapy at the chinics of the Post Graduate, St Lukes, and Reconstruction Hospitals Autogenous and different stock vaccines have been used and administered subcutaneously and intravenously A complete survey of the therapeutic results, and a comparative study of vaccine and other forms of treat ment will be published later Quoted here are only the results of vaccine therapy of one hundred cases from the clinic of the They correspond Lukes Hospital findings of approximately with the Stamsby Nicholls (Table II) It was interesting to observe that normal saline injections were as effective as the different vaccines For control purposes in several cases the same patient was given a series of normal saline injections after a series of vaccine-without informing hm-and nearly every case showed the same improvement or retrogression as with vaccine This fact alone proves that vaccine did not produce in the above mentioned cases any specific effect. The improvement and "better feeling' were due perhaps to the psychological effect of an intravenous or subcutineous injection

Comment

Vaccine therapy is based on the as sumption that nonspecific chronic arthritis

appears to be due to a bacterial infection, although so far there is no definite proof of a single specific bacterium causing the disease

The method of administration and dosage is also unsettled. The concensus of opinion inclines to accept the intravenous method, giving small dosages of vaccine over a long period of time, avoiding pronounced constitutional, and especially joint reactions.

Since none of the vaccines can be accepted with justification as specific, it is difficult to decide which type of vaccine should be administered. At present there are no laboratory or immunological ways to compare the therapeutic value of the different vaccines, and there are favorable results and failures reported with each and all If it should be eventually determined which strain plays a definite etiological role, production of a high degree of active immunity against it, with a properly prepared vaccine, would prob ably be an effective specific therapy Until then all extravagant claims of specific vaccine effect should be discarded

The specific indications for the use of vaccine therapy are still an open question Some workers use it in every case and type of arthritis, while others totally disregard it In spite of the fact that the therapeutic results of vaccine therapy do not prove to be more effective than other forms of therapy, I believe it is a useful adjunct to our present method of treatment We should give it a fair trial in all cases of rheumatoid arthritis and it can be employed in every type of arthritis where a nonspecific protein therapy is indicated We should not expect that vac cine alone will cure arthritis, but besides the direct therapeutic effect, it has the great advantage that during a series of

SIXTH INTERNATIONAL CONGRESS ON PHYSICAL MEDICINE

The Sixth International Congress on Physical Medicine will be held in London, May 12-16, 1936. It will consist of sections on kinesitherapy, physical education, hydrotherapy and climatotherapy, electrotherapy, actinotherapy, radiotherapy and radium

American participants will sail therapy. from New York on May 2nd on the MV Britannic and return on May 31st on the SS Transylvania. Dr. Richard Kovacs, 1100 Park Ave., New York, is Executive of the American Committee.

DR. RAYMOND TO HEAD SEARLE RESEARCH

Announcement has just been made by G. D. Searle & Co., Chicago, of the appointment of Dr. Albert L. Raymond as Director of their Research Laboratories.

To take this Searle appointment, Dr. Raymond resigns from the Rockefeller Institute of Medical Research, with which he has been connected for the past nine years, the last seven of which he was an associate of Dr. Levene.

For two years he was National Research fellow, working on problems connected with the biological mechanism of carbohydrate degradation.

Dr. Raymond is a Californian and gained his Ph.D. at the California Institute of Technology, Pasadena in 1925. Afterwards he spent three years part-time teaching at California Institute of Technology and at the University, of California.

He is a member of the American Chemical Society and the American Society of Biological Chemists.

Says Dr. Raymond:

"I know of no field offering greater facilities for the practical application of biochemical research than the laboratory of a pharmaceutical house. Here we come in first hand contact with the problems of that working scientist, the practicing physician, and this is a great incentive to provide him with better chemical instruments with which to fight disease."

The minister sees people at their best, the lawyer sees them at their worst, the doctor sees them just as they are—Dr. James B. Herrick.

BACTERIEMIA FOLLOWING INSTRUMENTATION OF THE INFECTED URINARY TRACT

JOHN H. POWERS, M.D., Cooperstown

Early Conceptions of Catheter Fever

A most interesting and somewhat acrimonious discussion of the etiology of catheter, or urinary, fever was initiated by some remarks of Sir Andrew Clark¹ before the Medical Society of London in 1883. In his historical resume of the subject Sir Andrew stated in brief:

In 1780 it was known, but not distinctly expressed, that surgical interference with the urethra and bladder was sometimes, and in certain circumstances, followed by an irritative fever. It was not, however, until 1810 that Moffatt, as quoted by Valpeau, described a case of chronic stricture of the urethra in which simple catheterism was followed by rigors, irregular fever, purulent arthritis, and death. In 1832 Brodie distinctly mentioned the dangers of catheterism and described as occasionally occurring in consequences of it paroxysms of irregular fever like ague, leading sometimes to prolonged debility, sometimes to continued fever with rheumatic pains, and sometimes even to mania. He further stated that in some cases death followed. Valpeau entered much more minutely into the nature and relations of the fever. He alleged that in some perfectly healthy persons even easy catheterism may develop a consecutive and con-tinuous fever and that this fever has five vari-eties. In the first it consists of a single paroxysm, ending in malaise and debility, with paroxysm, ending in malaise and debitity, with recovery in a few days. The second consists of recurring paroxysms issuing in continued fever which is oftentimes fatal. The third con-sists of an inflammatory fever arising out of nephritis, phlebitis, or other local inflammation. The fourth is associated with purulent arthritis. The fifth consists of a rapid succession of violent paroxysms speedily ending in collapse and death.

Valpeau then points out, and very clearly, that in the second and fifth varieties he has never found present at the autopsies an adequate structural cause of death, and in those cases he is disposed to regard the origin of the fever as caused by the absorption of vitiated urinary constituents.

Thus we find the symptoms of "urinary fever" presented more than one hundred years ago and described so accurately that we are able to recognize from these careful observations two distinct types of pathological processes; (1) the general symptoms secondary to a primary ascending infection or the

superimposition of such an infection upon chronic renal disease and (2) symptoms which suggest the development of bacteriemia occurring shortly after urethral instrumentation in the presence of chronic cystitis.

In 1867 Sir John Fayrer² declared that the predisposition to catheter fever lay in the malarial state and its consequences, or else in incipient or advanced diseases of the kidneys or other parts of the urinary tract; that it began (and from him we have a new opinion regarding its etiology which persisted for many years) in a reflex disorder of the nervous system; that it was not due to toxemia, and that catheterism alone, without injury or sensible irritation, was in these circumstances sufficient to originate the febrile phenomena.

In these statements we find a differentiation in the types of urinary fever, the first of which was believed to be due to chronic renal disease and the second of which, for want of a more satisfactory explanation, was attributed to malaria or a reflex disorder of the nervous system. During the next several years the nervous theory acquired more and more adherents.

In 1877 Marcus Beck,2 describing the fever in which death may occur in from nine to forty-eight hours, stated that the predisposition to it lay in chronic disorders of the health, renal imperfections, and age; that the exciting cause was probably mechanical injury of the urethra, and that the fever was begotten through irritation of the spinocerebral and sympathetic nerves reflected upon the kidney.

All these authorities add that in a small but noticeable percentage of cases no adequate structural cause of death was found. Such was the knowledge of catheter, or urinary, fever during the last quarter of the last century.

With the development of the sciences of bacteriology and experimental surgery numerous contributions were made to the

From the Defartment of Surgery of the Mary Imogene Bassett Hospital, Cooperstown, New York. Read at the Annual Meeting of The Medical Society of the State of New York, Albany, May 15, 1935. pathology of the urinary tract. In 1898 a case was recorded by Moullin⁸ in which a small polypoid outgrowth from the neck of the bladder was removed through a perineal incision. A considerable amount of postoperative venous oozing occurred and the blood, coagulating in the prostatic urethra, caused straining. Two days later a rigor set in and from that time, during the six weeks that the patient lived, the temperature was exceedingly irregular, and the pulse rapid. Moullin goes on to state:

Throughout the whole time the urine was acid but it was loaded with long slender bacilli which, from my later experience in connection with them, I have little doubt were the bacteria coli and from the intensely offensive character of the intestinal contents, a peculiarly virulent form of it. During the straining that followed the operation, it seems probable that some of these virulent bacilli were forced into the open ends of the veins at the neck of the bladder and caused general septicemia. And there can be little doubt that the rigors that occur after internal urethrotomy and after operations upon the kidney, involving the opening of large and deep seated collections of pus are due essentially to the same cause, either the toxic products of the organisms or the organisms themselves being forced into the circulation.

These statements suggest a clear recognition of the dangers of septicemia following *open* operations upon the infected urinary tract.

Review of Recent Literature

Early in the present century appeared definite bacteriological evidence to support the numerous clinical observations of the past that the same complicating septicemia may follow closed instrumental procedures. In 1902 Bertelsmann and Mau⁴ reported three cases of urethral fever in which positive blood cultures In one of these the were obtained. urethra was dilated for stricture; five hours later the patient made an unsuccessful attempt to void and one hour subsequently had a severe chill. Culture of the blood taken during the rigor yielded large numbers of staphylococci and B. coli. A second dilatation was uneventful but a third, two weeks after the first, was followed by another chill twelve hours later and the patient subsequently died of staphylococcal endocarditis. These

Tabulation of thirty cases in which blood cultures were taken immediately and one hour after instrumentation of the infected, male urinary tract. Transient bacteriemia occurred in cases 3, 9, and 11, an incidence of ten per cent.

authors expressed the opinion that the bacteria entered the blood stream from traumatized areas in the urethra

A paper by Crabtree in 1916⁵ included reference to seven cases in which positive blood cultures were obtained during the course of vesical drainage through an inlying urethral catheter Thirteen years later appeared the splendid work of Scott⁶ at the Brady Urological Institute in Baltimore He believed that many tem porary blood stream infections escape recognition and instituted routine measures for their detection During a period of two years immediate blood cultures were taken from every patient with a chill or a temperture of 102°Γ or above, positive cultures were obtained in 82 cases In 1932 Hyman and Edelman⁷ reported positive cultures from sixty four patients with disease of the urmary tract during a period of fifteen years at the Mount Sinai Hospital in New The cases from these two series in which the infection of the blood stream followed only closed operative and instrumental procedures have been tabulated (Table II) and will be analyzed in the discussion below To them have been added a similar group from a smaller series reported by Barrington and Wright's and four cases from the author's studies which are herein recorded The first case is an unquestionable example of bicteriemin following instrumentation of the infected urinary tract

Report of Case

M G (History No 8539) The patient, a married womin, iged 45 years, was admitted to The Mary Imogene Bassett Hospital for the second time on June 28th, 1933, because of pun in both flanks and the right costovertebral angle Burning, frequency,

Clart of patent No 8539 slowing relation of postcystoscopic symptoms and fever to positive blood cultures

Group of fifty four cases of bacteriemia following closed operative manipulation of the infected urinary tract "Death was due to a later operative procedure and not to septicemia. The mortality rate in the other fifty two cases was 115 per cent.

nocturia, and suprapublic discomfort were distressing, hematuria occurred once Physical examination revealed tenderness in both flanks, both costovertebral angles, in the suprapubic region, and along the urethra

The temperature, pulse rate, and respiratory rate were normal A specimen of urine obtained by catheter was slightly cloudy, acid in reaction, had a specific gravity of 1011, and contained a very slight trace of albumin Microscopic examination of the centrifuged sediment showed tenforty single and clumped pus cells per high power field No acid fast organisms were

found Culture yielded Escherichia coli There was no anemia or leukocytosis The Wassermann reaction was negative The renal function by the phenoisulphonphthalein method was seventy-five per cent and the nonprotein nitrogen of the blood was twenty-four mg per one hundred cc Cystoscopic examination was performed

on the third day after admission. No reaction occurred and the examination was repeated four days later. The cystoscope was introduced without difficulty and with no undue trauma. The trigone was red and granular in appearance but elsewhere the

vesical mucosa was normal. Catheters were passed up to each kidney and separate urinary samples were collected. The urine from the right side was brown and turbid; the left, clear and straw-colored. Escherichia coli was obtained from both specimens and from the bladder; no acid fast organisms were seen, and postmortem examination of inoculated guinea pigs subsequently revealed no tuberculosis.

A pyelogram was taken after the injection of seven c.c. of ten per cent sodium iodide through the catheter in the right ureter. The patient complained of some pain in the flank after six c.c. had been introduced into the pelvis of the kidney and the last cubic centimeter was injected slowly into the ureter as the catheter was withdrawn. The procedure was repeated on the left side but in this instance the pain was located in the lower abdominal quadrant. The deformity of the right upper major calyx was essentially the same as when first noted five months previously. There was no definite abnormality of the left pelvis. No extravasation of sodium iodide into the substance of either

kidney was apparent.

328

The second postcystoscopic period was exceedingly stormy. The patient complained of severe pain in the back, was nauseated, and vomited during the evening. The temperature rose to 101°F. at 8 P.M. to 103.2°F. at 4 the next morning (see Chart) and continued upward within the next thirty-six hours to a peak of 106.2° during a chill in the evening of the second day. The leukocytic count was elevated. Nausea and vomiting persisted; abdominal pain, tenderness, and spasm were present, most marked in the right flank and costovertebral angle. Blood cultures were positive for Escherichia coli twenty-four hours after cystoscopy, again the following evening one and one-half hours after the chill, and again six days later. The number of pus cells in the urine was increased for several days and red cells were present for seventytwo hours after cystoscopy. The symptoms gradually disappeared and the temperature subsided by lysis to normal on the eleventh day.

Comment. This patient developed bacteriemia due to Escherichia coli subsequent to cystoscopy and retrograde pyelography. In view of the early onset of pain in the right flank and costovertebral angle, and the later localization of tenderness and spasm in this region, the most probable portal of entry was the right renal pelvis. One may only surmise whether the predisposing factor was due to overdistention of the pelvis with pyelo-

graphic fluid or to acute exacerbation of a chronic pyelitis due to irritation of the inflamed epithelium by injection of a foreign medium. At any rate, this case represents a definite type of postinstrumental complication in urological practice, the frequency and dangers of which are often minimized or unrecognized.

Clinical Studies

In view of the interest aroused by this case a clinical investigation was carried out with a group of male patients on the urological service of the Mary Imogene Bassett Hospital, to obtain some information regarding the frequency of postinstrumental bacteriemia and to determine if transient bacteriemia may occur without clinical evidence of generalized sepsis. Chronic infection of the urinary tract, proved by the culture of bacteria from a catheterized specimen of urine, was present in every instance. No cases were included in which open operations were performed or in which prostatic or periurethral abscesses were present. Instrumentation of the urethra was either the major purpose of the operation or an incidental necessity.

A clean specimen of urine Method.was obtained by catheter, or through the cystoscope, for culture. Immediately after the instrumental procedure had been completed, and before the patient was removed from the cystoscopic table, the skin on the flexor surface of the elbow was cleansed with alcohol, a tourniquet was applied, and ten c.c. of blood were withdrawn from a vein in the cubital fossa. Five c.c. were deposited in each of two flasks containing beef infusion broth and incubated at 37° C. for ten days. Blood was withdrawn again one hour later and two more flasks were inoculated. When a positive result was obtained, subcultures were made and the organism was

identified.

These studies were carried out after thirty closed operative manipulations in the presence of urinary infection.

Results. The urological diagnosis, type of urinary infection, the instrumental procedure, and the cultural results are tabulated in Table I. Immediate positive cultures of Escherichia coli in one flask only were obtained in two cases after dilatation of an urethral stricture and both

the immediate and later cultures were positive for Pseudomonas aeruginosa in a third case, an incidence of ten per cent It is quite within the realm of possibility that these positive results were all due to contamination. Escherichia coli is not a frequent contaminant, however, and while pyocyaneous is, its presence in both the immediate and late cultures is rather against this presumption

Consequently the author feels that, although the series of observations is small, the results suggest that (1) transient, usually unrecognized, invasion of the blood stream may occur after instrumentation of the infected urinary tract. (2) the invading organism may be that which is responsible for the urinary infection, and (3) the portal of entry is probably through minute abrasions in the

urethral mucosa

Furthermore the case reported in detail above offers definite evidence that a more prolonged and serious bacteriemia may occur following retrograde pyelography in the presence of chronic pyclitis

Discussion

For the purpose of studying a larger group of cases than has come within the personal experience of the author those cases have been selected from the reports of Scott,8 Hyman and Edelman7 and Barrington and Wright^a in which infection of the blood stream followed only closed operative and instrumental procedures These, with the four recorded above, make a total number of fifty-four cases (Table II). They have been classified according to the urological diagnosis (Table III), the instrumental procedure

Urological Diagnosis	Num- ber	Per cent

Fifty four cases classified according to the urolological diagnosis. Urethral structure and benign prostatic hyper-trophy comprise 59 2 per cent

(Table IV), the probable portal of entry (Table V), and the type of organisms isolated from the blood (Table VI), and from the urine (Table VII). Analysis of these tables discloses a few outstanding facts:

1. Stricture of the urethra and benign hypertrophy of the prostate were the major urological diagnoses in 592 per cent of the cases (Table III.)

- 2. Dilatation of an urethral stricture, cystoscopic examination, and the use of a retention catheter were responsible for 81.5 per cent of the bacteriemias (Table IV.)
- 3. The urethra was regarded as the probable portal of entry in 83.3 per cent of the cases (Table V.)
- 4. Organisms of the Escherichia group were isolated from the blood stream in fifty per cent of the cases and staphylococci or unidentified cocci in 20.3 per cent (Table VI.)
- 5. Escherichia coli or unidentified bacilli were responsible for 48.5 per cent of the urinary infections and staphylococci or unidentified cocci for 20.6 per cent (Table VII.)

It is probable from the author's clinical studies recorded above, as well as the work of Barrington and Wright, that organisms may be detected in the peripheral blood very soon after instrumentation of the infected urinary tract. Furthermore these organisms soon disappear unless a permanent focus of infection be present to act as a constant source of supply, a fact which suggests that cultural examination of the blood should be made within a few minutes following the operative procedure in order to yield positive The fact that positive cultures may be obtained so soon after instrumentation presupposes invasion by the direct route rather than by the more circuitous lymphatic channels. Such a transient bacteriemia presumably occurred in ten per cent of the author's small series of thirty cases studied and in a higher percentage of Barrington's group. Subjective and objective constitutional symptoms may be absent. Barrington and Wright have also demonstrated a fact which has been recognized clinically for many years, that similar invasion of greater severity may take place during the first natural micturition following urethral instrumentation. Fever and rigors do not necessarily occur with such bacteriemias but appear to depend on the number of invading organisms.8 It is probable that the rigor,

when present, is due to destruction of the organisms and release of their toxins rather than to their primary dissemination in the circulating blood.

As the source of invasion is the infected urinary tract traumatized by instrumentation and the probability of invasion is directly proportional to the amount of trauma inflicted, one may conclude with reason and reiterate with emphasis that gentleness and caution are of the utmost importance in instrumentation of the infected urinary tract.

Summary

- 1. A case of bacteriemia following cystoscopy and retrograde pyelography has been described in detail.
- 2. The early conceptions of "catheter fever" have been presented briefly.
- 3. The method employed in the study of thirty cases in which closed operative manipulation of the infected urinary tract was carried out at the Mary Imogene Bassett Hospital, has been described and the results have been tabulated. Positive cultures were obtained three times, an incidence of ten per cent.

Fifty cases of bacteriemia following instrumentation have been collected from the recent literature. These with the four recorded by the author, have been classified and analyzed according to the urological diagnosis, the instrumental procedure, the portal of entry, the type of blood stream infection, and the type of urinary infection.

It has been concluded that transient or temporary bacteriemia is not rare, that it is often not followed by generalized symptoms of sepsis, that infected urine and urinary passages are the source of the invasion, that instrumentation is the precipitating cause, that the probability of invasion is directly proportional to the amount of trauma inflicted, and that gentleness and caution are of the utmost importance in preventing the occurrence of such postinstrumental bacteriemia.

Discussion

Dr. James H. Borrell, Buffalo-I wish to congratulate Dr. Powers on his very excellent paper, which again calls to our attention the bacteriological findings on a much discussed subject and one that has always been accepted as one of the hazards of the instrumentation of the uninary tract.

My personal experience has been that frequently, individuals with apparently noninfected urinary tracts, have more stormy postinstrumental courses than those patients with obviously infected tracts. The probable answer to this is that the infected patient has established an immunity, or some sort of a defense mechanism. It is usually conceded that urethral chills are probably due to a pyelonephritis, with or without an ac-companying bacteriemia. The condition is, in all probability, brought about by extension of the infection along the lymphatic channels accompanying the ureters or by direct reflux from the bladder. I have had no personal experience with the bacteriological findings in these cases except the usual routine laboratory procedures.

I should like to emphasize particularly Dr. Powers' conclusion, "That gentleness and caution are of the utmost importance in preventing postinstrumental complications."
It would seem fitting at this time to make

a few suggestions regarding the treatment of patients about to be cystoscoped. Very few cystoscopic examinations are emergency cases, and I feel that pre-cystoscopic attention to the gastrointestinal tract, a preliminary urinary antiseptic for one or two days, and a careful search for other foci are important. Frequently, in cases where retrograde cystoscopy does not seem advisable, much and sometimes sufficient information may be obtained from intravenous urography. A sedative, not necessarily morphine, given one hour before cystoscopic examination aids materially with apprehensive patients; and the use of a local anesthetic, such as diothane, cocaine or novocaine, tends to remove the natural resistance of the patient and thus lessens the chance for trauma.

In an obviously badly infected kidney, the use of an inlying ureteral catheter for twenty-four to forty-eight hours frequently prevents post-cystoscopic mishaps. I would advise caution against the continued use of inlying urethral catheters in those individuals who obviously do not tolerate them, as evidenced by the prompt appearance of urethritis and lymphadenitis.

We all exercise every care in doing pyelograms and I have personally always felt that, when the x-ray man could visibly demonstrate pyelo-venous backflow or pylelotubular back flow or extravasation or pyelographic spill or whatever you choose to call it, we were inviting complications.

I recently selected ten cases in which there was some evidence of pyelographic extravasation, but curiously enough, none of these patients showed any unusual post-cystoscopic complications. The highest temperature was 100 2° F, and that in only one case: most of the others not showing any febrile disturbance.

In conclusion, we must remember, however, that, as in all infections, the factor of individual resistance, the susceptibility of the patient, and the pathogenicity and number of organisms liberated probably govern to a large extent what the postcystoscopic course will be.

COMPENSATION LAW GETTING INTO ITS STRIDE

State Industrial Commissioner Elmer F. Andrews has served notice on all employers who are self-insurers that they must post notices informing their employees that they have free choice of physician in case of injury.

Due to the amendment of the Workmen's Compensation Law permitting injured workmen a free choice of attending physician, selected from panels of qualified physicians, a new unit, known as the Medical Registration Unit, was established. Through this Unit authorization to practice in compensation cases has been issued to approximately 8,000 physicians in the New York City District; 1,500 in the Albany District, and approximately 1,200 each in the Buffalo, Rochester and Syracuse Districts; a total of 13,253 physicians, according to incomplete figures.

As a result of investigations by the Division, the Attorney General's office has secured convictions against over 400 employers who sought by subterfuge to avoid compliance with various provisions of the Workmen's Compensation Law,

Victor Hugo said: "The misery of a child is interesting to a mother; the misery of a young man is interesting to a woman; the misery of an old man is interesting to nobody." Except-he might have added-the doctor.

ACUTE APPENDICITIS IN INFANTS AND CHILDREN UNDER FIVE YEARS OF AGE

JAMES HARRY HEYL, M.D., New York City

So much has been written on acute appendicitis and so many statistics compiled that one hesitates to add a small series. In recent years attention has been drawn to the increasing mortality, in the United States and elsewhere, by Willis, E. L. Eliason,⁵ Thomas Ryan,¹³ and many others. Opinion in general attributes this increase largely to the surgeon.

Eliason writes:

Probably the fact that appendicitis is no longer, generally speaking, considered a major surgical condition, and today is undertaken by hundreds of inexperienced operators as lightly as they undertake an amputation or a herniorrhaphy, accounts for some of the increase. Credence is to be given to this idea because, although the country wide mortality at the hands of the vastly increased number of inexperienced surgeons is higher, yet at the same time that of the big clinics and experienced men has decreased.

There is probably another cause for this increase, especially among infants. Ryan has shown that in Philadelphia in 1928 the mortality rate in patients between two and five years of age was eighty-one per cent higher than in 1923; five and ten years of age, forty-seven per cent higher; ten to fifteen years the same, and over fifteen years eighteen per cent lower, while during the later period the total rate for all was a little lower. Such conflicting figures require interpretation. Is it not reasonable to assume in the face of a lowering of the mortality in the group as a whole, that some other factor than the surgical treatment must account for the rise in the mortality in the younger age groups? As the surgical treatment is not essentially different for the different ages, is it not fair to believe that the increased mortality is due to the increased incidence resulting from more frequent recognition? It has been suggested that modern diets in infancy may increase the incidence of appendicitis. Inasmuch as these diets cause an increase in pathogenic bacteria of the colon type, there are grounds for this supposition.

It has been shown emphatically that in

the two extremes of life acute appendicitis is a much more serious disease than in the intervening years and the diagnosis more difficult. We will limit the discussion only to the group under five years of age.

The cases reported by Abt in Table I were largely culled from the literature and represent the largest series that we have found under two years of age. The earliest case in the series occurred in 1847 and many of the others before the pathology was generally understood. Twenty of his collected cases were under three months of age showing clearly that acute appendicitis must be considered a possibility from birth onward. Over one-fourth of his cases were diagnosed at autopsy.¹

Beekman's cases are of particular interest because of the excellent follow up, 126 of a total of 146 cases. All of his cases (21) under six years of age had perforated, and sixty-seven per cent of the entire series. He found the disease twice as common in males as females and the mortality twice as great in females. Herniae followed operation in sixteen cases or 12.7 per cent.²

cases, or 12.7 per cent.²

There are many factors which are responsible for the high mortality in the earliest age group. The most important factors, namely the duration of the disease before medical aid is sought and treatment with cathartics, are common to all ages and do not require further comment. The causes more peculiarly associated with infants are the increased difficulty in

diagnosis which Bolling well states is inversely proportional to the age, the relatively short duration between onset symptoms and rupture, and the comparatively feeble defense of the child's

peritoneum 3

The present study is based on ninety unselected consecutive cases of authenticated acute appendicitis, under five years of age, eighty-five at St. Mary's Hospital for Children in the past twelve years, and five at the Beekman Street Hospital in the past six years, operated on by their surgical staffs. All cases in which the pathological examination was questionable have been excluded

Occurrence

As would be expected the frequency of the disease in our series rises proportionally with the age, the increase being sharpest in the first three years and thereafter approaches more and more gradually its maximum incidence from the fifteenth to the thirtieth year

TABLE II

	Cases	Per cent Cases	Deaths	Mortal ty
Male	59	65 5	7	11 86
Female	31	34 5		12 91

Sev In our series as in most others the disease was more common in the males, approximately two thirds occurring in that sex. Unlike many others the mortality in the two seves was practically the same (Table II) Most commentators have found the mortality higher among females. We are not aware of any explanation for this discrepancy. Maes' figures showed 148 males to 102 females, with a female mortality 88 per cent, to 67 per cent in the males.

History We must depend on the observation of the parents for the earliest symptoms. They frequently delay calling a physician because of the frequency of vonting, abdominal pain, and fever as reactions out of all proportion to stimuli of improper feeding and the toxins of other diseases. In this series, pain and vomiting were the outstanding symptoms. Pain was the first symptom noticed in two thirds of the cases. The others noted in order of their frequency were anoresia, apathy, fever, lameness, constipation, diarrhea,

and abdominal injury. The most prominent symptoms on admission were pain and vomiting followed in order by fever, anorexia, diarrhea, apathy, dysuria, lameness, convulsion, constipition, flexion of thighs, and irritability. Attention should be called to diarrhea, not because of its frequency, but because it does not fit in with the picture of the pathology. In 8 cases it was a prominent symptom, 3 had spreading peritonitis, 2 localized and spreading peritonitis, and one localized peritonitis, and 2 unruptured acute appendictits.

Previous attacks were mentioned in 6 cases, or 647 per cent. In only 2 was there more than one previous attack. One of the latter had had 5 previous attacks, and this was the only one of the 6 that required drainage. The occurrence of previous attacks was much more common in cases of subacute, chronic, and questionable pathology, but serious pathology may fol-

low previous attacks

Bolling³ found twelve per cent of his cases gave a history of previous attacks and he emphasized the fact that only the worst cases are recognized and reach the surgeon Maes¹⁰ found a history of previous attacks in 228 per cent of his series.

Catharsis Forty one cases received cathartics, often repeated, and often of a drastic nature, 9 did not. In the other 40 it was not mentioned in the histories It seems safe to assume that the great majority of these cases were so treated The only effective remedy to this situation is an attack on the cathartic habit. per se As long as the general public consider cathartics as a sovereign remedy for all the ills to which the flesh is heir, just so long will these cases continue to receive such treatment at home, before a doctor is called Such an attack seems an excellent idea, but it is questionable whether there is sufficient uniformity of opinion among doctors to permit effective propaganda against this ancient and quaint

Physical Examination The successful evaluation of the objective symptoms require of the examiner much patience, close observation, gentleness, and tact Much can be learned without handling the putient, as to the type of breathing, whether abdominal or thoracic, whether

the thighs are flexed on the abdomen, whether the child is suffering acute pain, whether apathetic or nervous, whether the abdomen is distended and whether he resents extension of the thighs, especially the right. Abdominal tenderness is often best shown by the attempt of the child to remove the examiner's hand when light palpation of the abdomen is attempted. The classical signs of localized tenderness and particularly rigidity may be entirely lacking especially in infancy. A rectal examination should always be made, and may be of great value in arriving at a diagnosis.

Fortunately the disease is relatively uncommon in the first or second year, one and 8 cases, respectively, in this series. Every one of those 9 cases required drainage. It is also significant that the youngest case of 11 months was observed on the ward of the hospital for 5 days before an exploration was carried out, and then considerable doubt was entertained as to the preoperative diagnosis. It is probable that most cases occurring in the first year and many in the second year recover or die without the correct diagnosis ever having been suspected. Abt has illustrated this conclusively in his series, over one-fourth of the 80 cases being diagnosed at autopsy, or half of the fatal cases.

Temperature. Temperature on admission varied from 99° to 106.4° F. by rectum, the average being 101.7°. The highest temperature was a case that entered the hospital in a moribund condition and died in three hours in spite of supportive treatment and on which no operation was attempted.

Leukocytosis. Blood counts were recorded in seventy-nine of the cases, varying from 6,000 to 44,300, with an average of 19,000. The percentage of polymorphonuclear leukocytes spread between thirty-nine per cent and ninety-six per cent, the average being seventy-nine per cent. The lowest count of 6,000 and seventy-five per cent polys was the only striking illustration of lowered resistance and a poor prognosis. It was a case of general peritonitis which died on the third postoperative day. The average of the ten fatal cases in which it was recorded was 14,580 and seventy-four per cent polys. The blood count is not of great value either in diagnosis or in prognosis.

The elimination of "a" and "b" from Table III which may be attributed to technical errors, gives the revised mortality statistics, which gives a truer picture of the mortality based on duration of symptoms.

The elimination of "c" gives a total operative mortality of 11.1 per cent.

The shortest duration of symptoms was one hour. On operation that case showed an appendicitis with an abscess which might be considered in the nature of a rebuttal. It is significant, however, that forty-four per cent of the nine cases of less than twenty-four hours' duration required drainage, seventy-five per cent between the first and second day, eighty per cent between the second and third day, 81.3 per cent between the third and fourth days, and one hundred per cent between the fourth and fifth days.

Only one-tenth of the cases were admitted during the first twenty-four hours and one-third in four or more days after the onset symptoms. The longest duration of symptoms was fourteen days. This child had a localized abscess and his only complaint was lameness. That the

⁽a) One case of unruptured acute appendicitis. Death followed secondary operation for pelvic abscess. (b) One case of unruptured acute appendicitis. Death followed secondary operation for general peritonitis. (c) One case of general peritonitis. Died three hours after admission without operation.

promptness with which operation is instituted after the onset of symptoms is by all odds the most important factor in preventing complications and lowering the mortality of appendicitis, has been recognized and re emphasized from the days of McBurney and J B Murphy to the present time

In this series as in most others, the general public is the worst offender, although the family physician is not entirely blumeless. It certainly speaks badly for the influence and publicity of organized medicine and public health agencies that competent medical aid is not sought more promptly and frequently.

We were surprised to find that nearly a guarter of the cases gave a history of respiratory infection. Only 2 cases of post operative pneumonia occurred and neither of these give any evidence of preoperative respiratory infection. While we are aware that others (Westermann) have some evidence to support a relationship in some cases between respiratory infection and acute appendicitis, we have no evidence in this series other than the high incidence of respiratory infection. This supports the belief that respiratory infection does not justify delaying operation in the presence of acute appendicitis It seems likely that many cases reported as acute appendicitis with general peritonitis are true streptococcus or pneumococcus peri tonitis which are frequently secondary to respiratory infections

Differential Diagnosis It would be in teresting and valuable to record all the mistaken diagnosis in which cases were operated on for acute appendicitis and other conditions found The filing of our hospital records makes that an almost in superable task and one has to full buck on personal experience and records of others Right lower lobe pneumonia is probably the most frequent cause of such errors Streptococcus and pnemococcus periton itis and mesenteric lymphadenitis cannot always be differentiated Paracentesis has real value in the peritonitis cases. Among the more bizarre errors in my experience are pericarditis typhoid fever, scarlet fever, early Potts disease (upper lumbar), a congenital cyst of the cecum in an in fant, and acute rheumatic fever, all of this group recovered in spite of the appen dectomy Pyelitis gastroenteritis, and in

tussusception are occasionally mistaken for acute appendicitis and must be borne in mind. By and large in the first two years of life, we believe the failure to recognize acute appendicitis is more common than the reverse, and certainly more disastrous in its consequences to the patient. Abdominal pain, vomiting, and fever lusting 24 hours or more in the absence of other demonstrable pathology justify exploration for appendicitis.

Operative Treatment Except for the case that was obviously moribund on admission operation was performed as soon as the diagnosis was suspected and irre spective of the stage of the disease Except in doubtful cases we prefer the McBurney incision. In this series two thirds of the incisions were of this nature, the remainder being rectus incisions largely muscle splitting, and only occasionally a Kummerer We can see little to recommend the so called Ochsner treatment, at least in young children. As the reasons for this belief rest on the pathology, its discussion might better be left to the discussion of that topic Only one case in this series remained in the hospital over 24 hours before operation that showed an abscess or general peritonitis. That case has been mentioned above and resulted in a mortality on the fourth day postoperatively Young children are very susceptible to dehydration and acidosis as a result of vomiting or diarrhea

For this reason especially, operative procedure should be simple and expeditious and anesthesia shortened Where an abscess is present, care should be taken to avoid breaking down adhesions and spreading the infection. When the child is toxic or the removal of the appendix difficult and prolonged it is far better to simply drain the abscess or the appendix region In 7 of these cases the appendix was deliberately left, and there were no mortalities in this group. One or two of the fatilities might have been avoided in this series had this procedure been followed It seems advisable to do a late appendectomy on these cases as there are records of severe recurrent attacks

Inversion is of doubtful value in any case, and not entirely without danger Where rupture has occurred it adds a few minutes to the operation, and simple ligation is preferred except in undrained

cases. Care should be taken to ligate flush to the cecum to prevent later infection of the stump (Cutler⁴). Where no abscess wall or sloughing tissues are left, and the cecum about the stump is not gangrenous no value is seen in draining the peritoneum in general peritonitis theoretically. In practice, however, we do not have the courage of our convictions and drain unless the child's general condition is good, feeling that the chief drawback to drainage is the loss of fluids which are easily replaced.

In accordance with Truesdell's¹⁴ idea we have discontinued draining the pelvis unless there is an abscess present in the pelvis with the feeling that an abscess is more likely to develop about a drain than if left undrained. Rolled rubber dam drains were employed in most cases and to this is attributed the avoidance of fecal fistulae in this series.

In drained cases Poole's teaching has recently been followed of not suturing muscles, fascia, or skin, packing the wound open down to the peritoneum with vaseline gauze. This was done in a few cases where the peritoneum was undrained, but where infection of the abdominal wall seemed probable. Unfortunately complete figures cannot be given on postoperative hernia, because of unsatisfactory follow-up; yet the author is convinced that less sloughing of fascia occurs and better healing of the abdominal wall ensues. There were no hernias in children since this procedure was adopted, but there was one in an obese, poorly developed adult. No evisceration has been seen following this method. There were 3 known postoperative herniae in this series, 2 of which were subsequently successfully repaired.

Pathology

No attempt has been made to draw fine distinctions between different stages of acute appendicitis, because for all practical purposes they are of little value, and such distinctions serve to confuse the issues depending as they must on the individual interpretation of the operators, and the accuracy of the operative records. Consequently we have roughly divided the cases according to the pathology into 3 groups; viz., acute appendicitis, acute appendicitis with localized peritonitis

(abscess), and acute appendicitis with spreading peritonitis. All are stages of the same pathological process which advance imperceptibly by degrees which are not clearcut and definite, and, even in such a rough classification, cannot be accurate.

The relationship between the duration of symptoms and the pathology has already been mentioned. The time element between the duration of the disease and rupture of the appendix in children is surprisingly short. The failure to form an abscess following rupture, or else effectually to wall off the disease in fifty per cent of the cases of peritonitis at the time of operation is especially noteworthy, and is much higher than in adults.

There are two obvious reasons for this in infants and young children. The peritoneum is less efficient in forming firm adhesions apparently in inverse proportion to the age. This is an advantage among the survivors resulting in very few cases of mechanical ileus, either immediate or late. None of the cases in this series developed a recognizable mechanical ileus. At secondary operations in children there is a notable lack of firm adhesions about the cecum as a residuum of the original pathology, nor have we ever encountered an ileus from postoperative adhesions in children.

The omentum often is not sufficiently long to reach the level of the appendix, as is the rule in later life. This lack of efficiency in limiting the spread of infection arouses skepticism as to the value of expectant treatment in spreading peritonitis in these cases. If there were any clinical signs by which one could determine with any certainty that a given case of spreading peritonitis would wall off the process, no one could argue successfully against expectant treatment in cases of spreading or general peritonitis. In the inability to recognize any such criterion, the author does not feel justified in giving expectant treatment a trial. Furthermore, in the hands of the inexperienced surgeon some cases under such a régime would be treated expectantly which have not ruptured, with diastrous results to the patients. In this connection attention should be drawn to the 2 cases mentioned above—the case with a 3 day history which entered the hospital moribund, and the youngest case which had been ill two days and was observed for 5 more on the ward and still had failed to effectively wall off the process Bolling, Keyes, and Beekman and most authors advocate immediate operation in all cases ın children

The accompanying table shows plainly that the bacteriology of these cases is far from satisfactory. In some no cultures were taken In some drained cases cultures were not reported, which unquestionably should have been positive. The only explanation for these negative cultures which can be offered is the failure to moculate media before they had dried out, and possibly bactericidal properties of the peritoneal serum in some cases with good resistance Forty-nine positive cultures were obtained, 23 of which were pure cultures, and 26 mixed The colon bacillus was the preponderant organism in forty-four cases Two undrained cases gave positive cultures of colon bacilli, one was uncomplicated, the other had an ab dominal wall infection. None of the gas bacillus type of organisms were identified, nor was there any clinical evidence of that type of infection A curious feature of the bacteriology was the finding of associated respiratory infection in only 2 of 16 cases in which organisms associated with that type of infection were recovered from the peritoneum

Morbidity The hospital morbidity, ex clusive of fatal cases, varied from 9 to 76 days with a mean of 26 The average might have been shortened considerably It has been the custom at St Mary's Hospital to prolong the hospital stay of patients whose physical condition and home environment were unsatisfactory, unfortunately a frequent finding

Secondary Operation Secondary operations in most cases were required for late peritoneal abscesses, 2 were perinephritic,

Total cases	23	26

3 were abdominal, 2 of which were opened through the rectum One ileostomy was performed for paralytic ileus, and one acute appendicitis without drainage was reopened because of a spreading peritonitis Three cases in which the appendix was not removed were readmitted later for appendectomy. One of these was operated on originally for a perinephritic abscess, the colon pus and the direction of the abscess tract giving the first clue to the primary disease Two postoperative hermae were repaired Secondary hermae should not be done for three months preferably more after complete healing of the abdominal wound because of the danger of secondary infection Colon bacillus infection in these hernia cases is quite common and suggest that the organisms remain dormant in the healed wounds for a considerable period

Seventeen cases suffered postoperative complications as shown in Table V Most of the complications were the direct result of the appendicitis. None of the coincidental complications resulted in a fatality The evisceration occurred in a child of 16 months, with a rectus incision and a Mickulicz drain on the eighth day postoperatively It was immediately sutured with through and through interrupted silk and healed firmly. It is worthy of note that no intestinal fistulae were still present at the time of discharge from the hospital nor were any operative closures required

Complications at the time of operation, except for respiratory infections, were few Three of the milder cases showed a mesenteric lymphadenitis at the time of operation One of the three was admitted 3 months after discharge with an attack of abdominal pain in the lower right quadrant which suggests that the original attack may have been due to lymphadenitis rather than appendicitis

Died four days after operation

(9) E D, 21/2 years old, admitted June 13 1929 Duration Three days Chief com plaint Abdominal pain Onset symptoms Apathy, vomiting, and pain the second day, refused to play Physical examination Slight distention, generalized rigidity of abdomen but most marked in right lower quadrant and right flank, right knee flexed, temp 1034°, W B C 10400, p seventyeight per cent lymphocytes, ten per cent large mononuclear lymphocytes, twelve per cent Operation June 13, 1929, right rectus incision, appendix ligated and excised, not inverted Mickulicz drain, time of operation thirty minutes Findings Acute gangrenous appendicitis with perforation and spreading peritonitis Result Died twenty four hours after operation

(10) M K, three years old, admitted September 26 1930 Duration Twenty four hours Past history Tonsillectomy and ade noidectomy September 23 1930 Onset symp toms Anorexia followed by pain and fever and vomiting Physical examination Ten derness and spasm in right lower quadrant W B C 9 400, p sixty eight, 1 thirty two Operation September 27, 1930, twenty-four hours after admission Course Rising temperature, distention, and persistent vomiting Findings Gangrenous appendicitis with spreading peritonitis Secondary operation

Postoperative treatment. The most important consideration in the postoperative treatment is the replacement of fluids, increasing resistance and maintaining the hydrogen-ion concentration of the blood. The author believes in the early administration of fluids by mouth.

After operation paralytic ileus is much more to be feared than the theoretical dangers of instituting normal peristalsis. When persistent vomiting precludes administration of fluids by mouth, transfusions, continuous saline infusions, and

clyses are of great value.

The value of glucose is still open to question. So far as we know the quantity of intravenous glucose which is available has never been accurately determined. Until such a determination has been made and the amount is or can be increased by the addition of insulin to a worth-while caloric value, it is open to question whether its administration is more beneficial than harmful. Adequate quantities of a five per cent glucose solution intravenously result in a spilling over through the kidneys. The ill effect of diabetes appears to be coincidental with hyperglycemia. Are the benefits sufficient to justify creating a hyperglycemia in infected cases? More than five per cent glucose solution in clyses is dangerous, and fatal complications were seen following even five per cent glucose clyses, prior to the use of the present purified product. The use of purified five per cent glucose clyses appears more logical than glucose infusions, but the quantity that can be given is necessarily much more limited.

A discussion of other postoperative

measures does not seem indicated.

The mortality in relation to duration of symptoms has been discussed above. There is a rise in mortality to the fourth day with a marked drop thereafter, only one death in thirty cases. These are cases of the mildest type who would probably recover without operation, or cases with good resistance that have been able to wall off the disease, and effectually combat

TABLE VI. MORTALITY ACCORDING TO AGE

Years -	Cases	Deaths	Per cent mortality
0-1	8	1	100
1-2		1	12.5
2-3	19	3	15.8
3-4	30	2	6.7
4-5	32	4	12.5

the toxemia. Their outlook is distinctly favorable (Table VI).

The mortality in respect to pathology is in accordance with expectations except for the ten per cent mortality in the unruptured cases. Both of these cases might be considered as possible unnecessary deaths. Both were acute cases with clear or slightly turbid fluid without any local peritonitis and neither were drained. One developed a general peritonitis and died five days after a secondary operation. The other developed a local peritonitis in the pelvis. This was opened the seventh day after the first operation through the rectum, the abscess having been discovered three days before. The abscess wall was tense, thin, and elastic. Death occurred twelve hours later with the signs of general peritonitis. It is probable that a few more days would have further walled off the process from the peritoneal cavity more safely (Table VII).

Case Histories of 11 Mortalities

(1) H. F., female, four years old, admitted August 15, 1921. Duration: Three days. Onset symptoms: Abdominal cramps and vomiting. Frequent catharsis. Pain and vomiting increasing. Physical examination: Abdomen distended; generalized tenderness and rigidity, most marked in right lower quadrant; temp. 102°, W. B. C. 22,000 p. ninety per cent, 1. ten per cent. Operation: McBurney incision, appendix excised; stump inverted; cigarette drain. Findings: Acute appendicitis with large localized peritonitis. Culture: Bacillus mucosus capsulatus. Result: Died four days after operation.

(2) J. T., male, four years old, admitted September 1, 1921. Duration: Three days. Onset symptoms: Lower abdominal pain followed by vomiting which persisted; castor oil. Physical examination: Not recorded; temp. 104°, W. B. C. 24,000 p. eighty-one per cent, l. nineteen per cent. Operation: September 1, 1921; McBurney incision; appendix retrocecal; appendix ligated and removed; not inverted; cigarette drain; time of operation, twenty-seven minutes. Findings: Acute perforated appendicitis with general peritonitis. Result: Died twelve hours after operation.

THE TREATMENT OF PLACENTA PREVIA BY CONSERVATIVE MEASURES

WARD L. EKAS, M.D., Rochester

From the Department of Obstetrics and Gynecology, University of Rochester School of Medicine and Dentistry

Hemorrhage, as a result of placenta previa, is one of the most serious complications occurring after the middle and particularly the latter third of pregnancy. The changing anatomical conditions in the uterus resulting in the stretching of the lower uterine segment make the hemorrhage inevitable and unavoidable. The first hemorrhage may be slight and go almost unheeded, or it may be fatal. Fortunately, the former is the more common. While other conditions may cause painless hemorrhage during the latter half of pregnancy, placenta previa should be the first considered and eliminated unless a more obvious cause is present to account for the bleeding. The hemorrhage should be taken as a warning that a placenta previa probably exists, and the patient kept under close observation until a definite diagnosis is made. Not occasionally the early threatened abortion becomes the placenta previa later in pregnancy,1

The methods of treatment are divided into two schools; the conservative, who favor obstetrical procedures aiming at delivery through the birth canal; and the surgical, who favor delivery by the abdominal route. There is a so-called third school who individualize each case in determining the method of treatment.²

The prognosis, for both mother and baby, is affected by other factors than the method of treatment, as, the amount of hemorrhage before, during, and after delivery, the duration of the pregnancy, the presence or absence of infection, the variety of placenta previa, the degree of separation, the dilatation of the cervix, the parity of the patient, the injuries to the birth canal, some other complication, and particularly the ability of the obstetrician.^{2,2}

The maternal and fetal mortality remains high regardless of the method of treatment. The maternal mortality is said to vary from one to nineteen per cent and the fetal mortality from ten to eighty per cent according to DeLee. Lack of unanimity on the methods of treatment, of course, means that each method has its shortcomings. The treatment used should aim at keeping the blood loss as low as possible until the uterus is emptied, as well as combating the anemia which frequently is present.

All agree that accouchement force no longer has a place in the treatment of this condition. Manual dilatation of the cervix, even from a partial to full dilatation is comparable to manual tearing. The dilatation must be slow and with uterine contractions, if delivery is to be effected through the birth canal without encountering dangerous lacerations. No attempt at delivery should be made until the

cervix is fully dilated.

Every case of placenta previa should be hospitalized. The home is no place to meet the energencies of this condition, if a hospital is available. Vaginal examinations should never be done until preparations have been completed to control bleading. A fatal hemorrhage may ensue before the bleeding can be controlled unless this precaution is taken. Rectal examinations, unless gently done, fall in the same category. Kellogge condemns them entirely in placenta previa.

The outline used by Holmes⁷ is followed for the most part in discussing the

methods of treatment,

1. Watchful expectancy has no justification once the diagnosis is established,8 unless the patient or relatives refuse to allow the necessary treatment to be carried out. The sudden, profuse, fatal hemorrhage can never be foretold.

2. Vaginal tamponade is a procedure of questionable merit. If used at all, it should be limited to the patient who is bleeding freely and must be transported a considerable distance to the hospital. Its

October 1; ileostomy under local anesthesia. Result: Died twenty-four hours after secondary operation.

(11) P. Z., 2½ years old, admitted August 30, 1933. Duration: Twenty-four hours. Chief complaint: Abdominal pain and vomiting; frequent catharsis and enema; pain worse. Physical examination: Generalized abdominal tenderness and rigidity; W. B. C. 17,900, p. eighty-eight, l. twelve. Operation: August 30, 1933; McBurney incision; appendix stump inverted; closed without drainage. Findings: Acute gangrenous appendicitis with sero sanguinous fluid. Culture: B. colon bacillus. Course: Septic tem-

perature rising; occasional vomiting September 5 rectal abscess palpated; two transfusions and many saline clyses. Secondary operation: September 8; abscess incised through rectum. Result: Died eleven hours after operation with hyperphrexia and symptoms of general peritonitis; autopsy refused.

Acknowledgment

The author wishes to express his appreciation to Dr. C. E. Farr, Dr. E. D. Truesdell, and Dr. R. H. Kennedy for permission to record these cases.

Not more than five per cent of persons suffering from arthritis can be classed as incurable in the light of modern knowledge and methods of therapy, Dr. Ralph Pemberton, professor of medicine at the University of Pennsylvania, said recently at the New York Academy of Medicine. Although he stressed the fact that there is as yet no cure for the disease, he pointed out that co-ordinated treatment based on careful analysis of the patient can achieve results today which would have been considered impossible a generation ago.

Large numbers of children suffering from serious brain conditions have been saved from death as a result of new methods of treatment developed at Temple University. Dr. Temple Fay, professor of neural surgery at that institution, told three hundred members of the Pediatric Section of the Kings County Medical Society recently. The treatment consists of relieving fluid pressure in the brain cavities by restoring a balance of fluids, allowing a normal flow of blood and oxygen to enter the head.

Twenty-one seniors in the College of Medicine at the University of Vermont are now out on extra-mural service, which is a unique part of their training for their profession, offering them practical experience that could not be obtained otherwise.

Extramural service is a form of training peculiar to the University of Vermont.

Senior students are placed for practical experience in the offices of various doctors in the smaller towns of the State, in each of the State institutions requiring medical service and in small town hospitals. They also do city service work in connection with the Burlington dispensary.

The students rotate, spending a month in each of the specified places. Half of the class goes out one semester and half the second semester.

The purpose of the new methods is to give the seniors special training of a sort they are likely to encounter in practicing in State like Vermont—learning at first hand the conditions under which their work is to be done and the problems they will be called upon to meet. The system of extramural service, to which a small rural State like Vermont admirably lends itself, has been built up with the idea of turning out not so much research men and specialists, but good general practitioners in medicine and surgery who can supply a growing need in the country districts.

Doctor Anthony Bassler has elected President of the National Society for the Advancement of Gastroenterology, President of the American Committee and United States Delegate to the International Society of Gastroenterology and Vice-Chairman of the Gastroenterological Section of the Pan American Congress.

THE TREATMENT OF PLACENTA PREVIA BY CONSERVATIVE MEASURES

WARD L. EKAS, M.D., Rochester

From the Department of Obstetrics and Gynecology, University of Rochester School of Medicine and Dentistry

Hemorrhage, as a result of placenta previa, is one of the most serious complications occurring after the middle and particularly the latter third of pregnancy. The changing anatomical conditions in the uterus resulting in the stretching of the lower uterine segment make the hemorrhage inevitable and unavoidable. The first hemorrhage may be slight and go almost unheeded, or it may be fatal. Fortunately, the former is the more common. While other conditions may cause painless hemorrhage during the latter half of pregnancy, placenta previa should be the first considered and climinated unless a more obvious cause is present to account for the bleeding. The hemorrhage should be taken as a warning that a placenta previa probably exists, and the patient kept under close observation until a definite diagnosis is made. Not occasionally the early threatened abortion becomes the placenta previa later in pregnancy.1

The methods of treatment are divided into two schools; the conservative, who favor obstetrical procedures aiming at delivery through the birth canal; and the surgical, who favor delivery by the abdominal route. There is a so-called third school who individualize each case in determining the method of treatment.2

The prognosis, for both mother and baby, is affected by other factors than the method of treatment, as, the amount of hemorrhage before, during, and after delivery, the duration of the pregnancy, the presence or absence of infection, the variety of placenta previa, the degree of separation, the dilatation of the cervix, the parity of the patient, the injuries to the birth canal, some other complication, and particularly the ability of the obstetrician.2.3

The maternal and fetal mortality remains high regardless of the method of treatment. The maternal mortality is said to vary from one to nineteen per cent and the fetal mortality from ten to eighty per cent according to DeLee. Lack of unanimity on the methods of treatment, of course, means that each method has its shortcomings. The treatment used should aim at keeping the blood loss as low as possible until the uterus is emptied, as well as combating the anemia which fre-

quently is present.

All agree that accouchement force no longer has a place in the treatment of this condition. Manual dilatation of the cervix, even from a partial to full dilatation is comparable to manual tearing. The dilatation must be slow and with uterine contractions, if delivery is to be effected through the birth canal without encountering dangerous lacerations. No attempt at delivery should be made until the cervix is fully dilated.

Every case of placenta previa should be hospitalized. The home is no place to meet the emergencies of this condition, if a hospital is available. Vaginal examinations should never be done until preparations have been completed to control bleeding.5 A fatal hemorrhage may ensue before the bleeding can be controlled unless this precaution is taken. Rectal examinations, unless gently done, fall in the same category. Kellogge condemns them

entirely in placenta previa.

The outline used by Holmes⁷ is followed for the most part in discussing the

methods of treatment.

1. Watchful expectancy has no justification once the diagnosis is established.8 unless the patient or relatives refuse to allow the necessary treatment to be carried out. The sudden, profuse, fatal hemorrhage can never be foretold.

2. Vaginal tamponade is a procedure of questionable merit. If used at all, it should be limited to the patient who is bleeding freely and must be transported a considerable distance to the hospital. Its

Read at the Annual Meeting of the Medical Society of the State of New York, Albany, May 14, 1935

value depends on placing the pack tightly against the cervix and holding it there by a tight T binder. Before insertion, the pack should be saturated with some antiseptic solution. Gauze is preferable, but cotton balls may be used. The patient can never be cleaned and draped so that the packing is surgically clean, and, as a result, sepsis is more apt to follow this procedure. It is a question whether it ever accomplishes its purpose and it not only wastes time but blood as well.

3. Artificial rupture of the membranes is particularly applicable to the marginal placenta previa, where the presenting part is fairly well in the pelvis and the patient in early labor. The membranes should be widely ruptured and a tight binder placed on the abdomen to help hold the presenting part against the cervix. In selected cases, the outcome is quite satisfactory for both mother and child.3

4. The Braxton Hicks bipolar version is a procedure requiring considerable obstetrical skill and its use is limited to the cases in whom the cervix is sufficiently dilated to permit the introduction of two fingers. It is of particular value in the case who is bleeding freely in the home;8 or in the hospital, when a Voorhees bag is not immediately available. A leg is brought down and the buttocks used to compress the placenta against the cervix. No attempt at extraction is made until the cervix is fully dilated. A weight may be tied to the foot to hold the buttocks against the cervix. The fetal mortality is definitely increased by this method of procedure.8

5. The use of the *Voorhees Bag* is limited to hospital practice. It can usually be introduced through the cervix with little or no dilatation beyond that already present. An anesthetic may not even be necessary. The size of the bag should be sufficient to insure complete dilatation of the cervix, that is, ten centimeters, when it is expelled. The membranes should always be ruptured so that the bag is intra-ovular, for in addition to stimulating uterine contractions and dilating the cervix, bleeding is controlled or stopped. Extra-ovular placing of the bag may cause further separation of the placenta and the bleeding is concealed. The patient must be closely followed and delivery promptly effected after expulsion of the

bag through the cervix, otherwise a profuse hemorrhage may occur at this time. Because of this possibility, everything must be kept in readiness for immediate delivery. Internal version and extraction is usually the preferable method of delivery, but if the bleeding is slight, and pains are of good quality, labor may be to terminate spontaneously. Forceps or breech extraction are done in selected cases.

6. Cesarean section. Four surgical methods are used: vaginal hysterotomy, classical cesarean section, low cervical section, and the Porro section. Numerous articles supporting one of these methods of treatment have appeared in the last few years.8,9,10,11,12

Vaginal hysterotomy has been abandoned because of the poor results and the technical difficulties of the operation in

the presence of placenta previa.12

The abdominal method of delivery is gaining more and more adherents. It cannot be denied that a primipara, who has a central or partial placenta previa and a living, viable child, should be considered for cesarean section, if the cervix is closed and there has been little bleeding.8 Williams¹³ states two indications for cesarean section: (1) the rare case of a primipara whose cervix is too rigid to permit the introduction of a Voorliees bag; (2) a complete placenta previa in a woman nearing the end of the child-bearing period, who is desirous of a living child. Bill,14 DeLce,4 Wilson,10 Siegel,0 and others are advocates of the surgical method. Both the classical and the low cervical sections have their proponents. Those favoring the low cervical section do so on the basis that bleeding can be seen and more easily controlled and that the danger of infection is less.2,4 The Porro section is limited, of course, to the case who is frankly infected or in whom it is desired to remove the uterus for other reasons. Seeley15 gives five contraindications to cesarean section: Shock from blood loss; (2) a cervix four cm. or more dilated in a patient in active labor; (3) if vaginal tamponade has been previously done; (4) if attempts at de-livery from below have been made; (5) doubtful asepsis from repeated vaginal examinations.

One cannot forget that cesarean section

carries with it a certain mortality, estimated by DeLee to be about four per cent but by Williams and Holmes to be ten per cent for all indications. Siegelo reports a series of 101 cases of placenta previa, all of whom were treated by cesarean section with only one death or a maternal mortality of less than one per cent. The fetal mortality was nearly twenty-five per cent. One must remember that the published results and advocates are by men highly trained in their specialty, and such excellent results would never be expected of the less expertly trained man.

This series of thirty-six cases is not presented with the idea of taking issue with those who believe in cesarean section, but to point out the value of the conservative measures. The surgically treated cases are more apt to be those having viable, living babies, leaving the others to be treated by obstetrical measures, with the resulting high maternal and fetal mortality. In this series, no case was treated by surgical measures, and it is of interest to note that not more than one premature baby could have been saved had the surgical method been used. The incidence of placenta previa was one in 147 or thirty-six in 5307 deliveries. In thirty-one cases or 86.1 per cent, a Voorhees bag was inserted to control bleeding and induce labor. In five cases a bag was not used, either because the diagnosis was not definitely established or the cervix was fully dilated when the patient was seen. Of the thirty-six cases, two have had a placenta previa twice on our service, and a third had a placenta previa at term in a previous pregnancy. One case had had a premature separation at term on our service in a previous pregnancy. Four cases were in primipara. Fifteen or 41.6 per cent had spontaneous deliveries and twenty-one or 58.3 per cent had operative deliveries. Four were central

placenta previas, ten partial placenta previas, and twenty-two marginal placenta previas. Table I shows the type of placenta previa and the mode of treat-

Manual removal of a part or all of the placenta, because of profuse bleeding, was necessary in four full term and five premature cases. In no case was it necessary to tamponade the uterus and vagina to control bleeding. Pituitrin, one or two c.c.. intramuscularly was given routinely, and ergot, if necessary, A prolapsed cord was encountered twice, and one of these babies was delivered alive by version and extraction. Two cases had cervical tears that were repaired. Twenty-eight cases were vertex presentations, seven were breech presentations, and one was a transverse presentation.

Age Incidence. Eleven cases were between twenty and twenty-five years of age, ten were between twenty-six and thirty, nine were between thirty-one and thirty-five and six were between thirty-six and forty.

Period of Gestation. Ten cases were from five to seven months, fourteen were from seven to eight months and twelve were from eight to nine months.

Duration of Bleeding. Of the thirty-six cases, thirteen had had bleeding for less than twenty-four hours before admission; five for from two to seven days; six for from one to four weeks and twelve for longer than four weeks. Two cases had had hospital admissions for threatened abortions earlier in the pregnancy. One other had been advised for admission for the same reason, but refused. A fourth had been in another hospital for the same reason.

The labors, as a rule, were short. Twenty-six cases had less than ten hour labors, and eleven of these were less than five hours. Six cases had labors longer than fifteen hours. The two longest labors, fifty-two and sixty-eight hours, were in primipara, both of whom delivered living term babies.

The maternal morbidity was high. Eighteen or fifty per cent of the cases had a febrile puerperium. One of these was possibly due to a respiratory infection and another to pyelitis. Four were only one day fevers. Twelve were intrauterine infections (see Table II). Two cases developed a thrombophlebitis, one after discharge from the hospital.

TABLE II-MATERNAL MORBIDITY

1—Febrile Cause not determined.
1—Pyelitis
4—One day fever
2—Intrauterine infections
1—Term—after bag insertion—Spontaneous.
5—Term—after bag insertion—Version & Extraction. One died.
1—Premature—after bag insertion—Spontaneous.
2—Premature—after bag insertion—Breech Extraction.
1—Premature—after bag insertion—Version & Extraction.
1—Premature—without bag insertion—Version & Extraction.
1—Immature—after bag insertion—Spontaneous.

There was one maternal death in this series, or a mortality of 2.77 per cent.

The patient was a thirty year old gravida one at term. The membranes had ruptured prematurely and there had been bleeding for three days before admission. The patient had washed the vagina and vulva with a wash cloth. She had a chill before admission and on admission to the hospital had an elevation of temperature. One vaginal examination had been done in the home. The bleeding had been considerable, the hemoglobin being 55 per cent. Her condition seemed good. Voorhees bag was inserted, and after a long labor, sixty-eight hours, delivery of a 3440 gm. living child was completed by version and extraction. The child died later of congenital heart disease. The placenta was manually removed, and not more than 300 c.c. of blood was lost at the time of delivery. She developed a hemolytic streptococcus septicemia and died. Six transfusions were given.

Fetal Mortality. Twenty-four or sixty-seven per cent of the babies were alive when born. One full term child died of congenital heart disease. Two premature and five immature babies died of prematurity. Babies weighing between 1500 and 2500 gms. are called premature and those weighing less than 1500 gms. immature. Twelve babies were still-born, and of these tẃo were term, four were premature, and six, were immature. Only one still-born was an intrapartum death, and it was a premature baby. Of this series, eleven cases were full term, fourteen were premature and eleven were immature. The uncorrected fetal mortality is twenty or 55.5 per cent. No other method of treatment would have saved more than one baby. Table III gives a summary of the fetal mortality.

TABLE III-FETAL MORTALITY

24 or 6673% of babics were alive when born
Nine—Full term—One died of congenital heart disease.
Ten—Premature—Two died.—Prematurity.
Five—Immature—All died.—Prematurity
12 or 3314% of babies were still-born.
Two—Full term—Dead on admission.
Four—Premature—Three dead on admission.
One intrapartum death.
Six—Immature—Two dead on admission.

Transfusions: From one to six transfusions were given in twelve cases. It is a wise precaution to group and match each case of placenta previa immediately after admission. By so doing, valuable time and perhaps a life may be saved later. Members of the family or professional donors may be used. The prospective donor should be kept at hand so that the emergency transfusion may be given, if it becomes necessary. Transfusions may be necessary to combat shock and hemorrhage before any operative procedure is carried out as well as after delivery. Either the indirect or direct method is used. Unquestionably many cases are saved by a timely transfusion, and its use is invaluable.1,5

The first danger to the mother is that of hemorrhage. The degree of separation of the placenta as well as the size of the sinuses opened determine the amount of bleeding. Any cervical tears from attempts at delivery through an incompletely dilated cervix add to this blood loss. Early appreciation of the importance of the first bleeding in the latter half of pregnancy cannot be stressed too strongly.5 Fifty per cent of the cases in this series had had bleeding longer than one week and 331/3 per cent for longer than four weeks before admission to the hospital. Only about a third entered the hospital with a history of bleeding less than twenty-four hours. The sooner the condition receives proper treatment, the less blood will be lost and also the less chance of infection. Because of the location of the placenta on the cervix, these patients are particularly apt to have puerperal infections. Add to this, attempts at treatment by inexperienced obstetricians under conditions as found in the homes or smaller hospitals and one can see the importance of infection in determining the prognosis. In this series of cases fifty per cent had a febrile puerperium and 331/3 per cent puerperal infections. The mortality was low, (2.77%) but this

345

one case died not from hemorrhage but infection. More cases are lost from infection than hemorrhage. Hemorrhage may be treated even in the home by a timely transfusion, if the precaution of having a donor ready has been taken. Vaginal tamponade, pelvic examinations, operative procedures, etc. should not be done under conditions where the technic is questionable. The greatest care must be exercised in maintaining asepsis in treating these cases. The frequency of infection makes cesarean section an even greater risk, except in well selected cases.

Fetal mortality is not dependent so much on the method of treatment, for many of the babies are premature or even immature, and a high percentage will die of prematurity.2.5,12 Of this series, only about thirty per cent of the babies were at term. The same number were immature, and in this group a mortality of approximately one hundred per cent is expected. Asphyxiation from separation of the placenta or hemorrhage is an important factor, as a third of the babies were dead on admission. Add to these two, the accidents of labor, even in cesarean section, and it is easily seen why the fetal mortality remains high. When we can decrease the mortality of premature babies, the fetal mortality in placenta previa can be decreased.

The advantages of the conservative or obstetrical proceedures, using the hydro-

static or Voorhees bag are:

(1) They can be used in all cases; (2) the bag controls hemorrhage and stimulates labor pains, thereby, dilating the cervix so that delivery can be completed without undue delay. The same is true for the Braxton Hicks bipolar version; (3) they incur less risk to the mother than surgical methods; (4) they require less technical skill than surgical treatment; (5) the presence of infection is not a contra-indication to their

The disadvantages of the Voorhees bag are:

(1) Some babies are lost by asphyxia from prolapse of the cord or from injuries in obstetrical procedures aiming at delivery. More babies are lost by the use of the Braxton Hicks bipolar version; (2) the rubber in the bags deteriorates rapidly, necessitating frequent replacement and inspection; (3) the use of the bag is limited to hospital practice.

The following is a summary of the pro-

cedure in treating a case of placenta previa by conservative measures: (1) Unless it is impossible, transport the patient to a hospital before carrying out any procedure. Rarely, if ever should the vagina be packed in the home; (2) be prepared to carry out a procedure necessary to control hemorrhage before doing a vaginal (or rectal) examination. Do the examination after a most careful clean up technic; (3) if the patient is in labor, and the presenting part fairly well in the pelvis, simple rupture of the membranes and the application of a tight abdominal binder will usually suffice to control hemorrhage in the marginal and perhaps the partial placenta previa; (4) if the patient is not in labor, a Braxton Hicks bipolar version may be done, or a Voorhees bag may be inserted. In the home the former is better, but in the hospital the latter is preferable. Delivery is attempted only after full dilation of the cervix, and then by the most conservative method; (5) have a compatible donor for immediate transfusion, if matching and grouping can be done; (6) watch for hemorrhage during the third stage of labor, and manually remove the placenta, if bleeding becomes profuse; (7) give a c.c. of pituitrin intramuscularly after the third stage of labor and the same amount of ergot if necessary to produce firm contraction of the uterus. It will seldom be necessary to insert an intrauterine pack, if the uterus is watched carefully and massaged; (8) cesarean section may be considered the procedure of choice in the occasional well selected case.

Summary and Conclusions

 A series of thirty-six cases of placenta previa is presented.

2. The maternal morbidity is fifty per cent, and the mortality is 2.77 per cent.

3. The uncorrected fetal mortality is 55.5 per cent.

 All the cases in the series were treated by conservative measures, and in eighty-six per cent the hydrostatic bag was used.

5. Two factors, prematurity and asphyxiation, keep the fetal mortality high.

 Not enough importance is attached to the initial hemorrhage in the latter half of pregnancy as approximately two-th

oses had bleeding for longer !

twenty-four hours before admission to the hospital.

- 7. Transfusions of whole or citrated blood are invaluable.
- 8. Only one premature child could have been saved, if cesarean section had been used. Death was due to prolapse of the umbilical cord at the time a Voorhees

bag was inserted.

- 9. The duration of labor, as a rule, is short.
- 10. Placenta previa should be treated by conservative measures in the large majority of cases and cesarean section used in the few well selected group.

Discussion

Dr. J. K. Quigley, Rochester—Dr. Ekas has presented an interesting series of cases of placenta previa. He has shown a very low maternal mortality rate for cases treated along obstetrical lines—a mortality rate of zero, from hemorrhage for thirty-six cases.

I prefer dividing the treatment into obstetrical and surgical if you will, rather than using the term conservative and radical. Delivery by the abdominal route in central placenta previa or placenta previa lateralis with a long undilated cervex is conservative and I feel that to empty the uterus by the vaginal route in such a case is radical rather than conservative.

Dr. Ekas said an advantage of obstetrics or conservative methods is that they may be employed in the home; as a matter of fact they must be and we are left with little choice but the Braxton Hicks. Every case of antepartum bleeding should be hospitalized if at all possible.

As I see it, there are about three elective procedures to be considered: (1) Rupture of the membranes, often sufficient in the marginal case; (2) the hydrostatic-bag; (3) cesarean section.

Bags I believe should be used for marginal or lateral placenta previa with a cervix partially dilated and obliterated, and in the obviously infected case. Cesarean section for all complete or central implantations and for many of the lateral variety where the cervix is long and undilated and bleeding is active and the case has not been tampered with. The operation should be preceeded or accompanied by transfusion.

I do not believe all cases of placenta

previa should be delivered by cesarean section but I will admit that the mortality rate of several series of cases so treated is quite impressive; for instance:

Bill in 1927 reported 45 cases prior to 1922 by various methods, 11.1 per cent maternal mortality; 56 cases treated 1922-1927, 72 per cent of them by cesarean section, maternal mortality of 1.78 per cent.

The mortality rate for central placenta previa is twenty to thirty per cent; for cesarean section, five per cent. One reason why I prefer cesarean section under the limitations I have outlined above is that it leaves a lower uterine segment, the site of the placental sinuses, undilated and untraumatized; most patients dying of placenta previa die of postpartum bleeding. Another reason is that in cases within a month of termination, it offers a better prognosis for the baby. Three points made by Dr. Ekas heartily endorse and wish to emphasize: (1) No vaginal examination except under absolute asepsis and then in the delivery rooms with all preparations made for immediate delivery; (2) never manually dilate the cervix even to complete a partial dilation; (3) always type the patient on diagnosis and have a donor at hand.

TREATMENT OF MOLES AND VERRUCAE

Trichloracetic Acid as an Analgesic Agent

ROBERT R. M. McLAUGHLIN, M.D., New York City

From the Department of Dermatology and Syphilis, Vanderbilt Clinic, Presbyterian Hospital, New York City

In the consideration of the removal of non-malignant moles and verrucae from the skin of the face, one has a choice of several recognized methods. The lesion itself, its duration, its location, the age of the patient, and the operator's clinical judgment determine just which method to use. It is not the purpose of this short paper to discuss the question of malignancy of moles, or even the various methods which are commonly used to remove skin tumors, but rather to present a simple method which appears to give excellent cosmetic results, with a minimum of discomfort to the patient.

The local injection of novocain, or other anesthetics, on many areas of the face, especially near the eyes, nose or mouth, even when one uses a very fine needle, is quite painful to most people. This injection also has the distinct disadvantage of producing a distorted field of operation.

A cursory review of the literature fails to show that trichloracetic acid, or the newer dichloracetic acid, has been used as an analgesic for subsequent desiccation with the Oudin current. Much has been written about the use of this acid as a keratolytic agent, even in conjunction with radium therapy (Aikins, 1 Iversen, 2 Fitzgerald, 3 Davis 1). The use of the chemical is not new in the treatment of certain lesions of the mucous membranes of the mouth, nose and throat. It is well known to rhinologists and laryngologists that this acid gives relief from pain when applied locally, especially to chronic ulcerations. A similar action may be expected when it is applied to the skin so that the deeper layers are affected.

Trichloracetic acid occurs as a white crystalline substance with a melting point of 55° C. It is not only readily soluble in water but is dequescent. Since there is usually some moisture on the skin, the small crystals seem to melt quickly when applied locally. The addition of a very

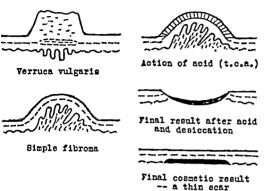

small quantity of water to the crystals, gives one a strong solution which is practically as effective and possibly more convenient to use.

Dichloracetic or bichloracetic acid is closely related to trichloracetic acid in its action and use and is possibly stronger in its escharotic action. This acid occurs as a clear, colorless, slightly viscid liquid. Both of these acids seem to be more keratolytic than the other commonly used preparations.

The method which I have used is as follows. If there is much hyperkeratosis the surface of the lesion is shaved down with a knife, scissors, or even a curette. The acid is then applied full strength to the surface of the lesion, using a toothpick or other suitable applicator. Care should be taken to avoid spilling the acid onto the surrounding skin. This may be prevented by ringing the lesion with vaseline. Even if a small amount does spill it may be neutralized readily with a bicarbonate of soda paste or with ordinary calamine and zinc lotion. Any bleeding which may occur following shaving will be controlled by the action of the acid.

After a minute or two, when the painted area becomes thoroughly whitened, it will be found that a degree of analgesia has developed, which, in most instances, is sufficient to permit light, interrupted desiccation. This light desiccation will increase the analgesic effect until a moderately strong current may be used without discomfort. A slight burning from the acid and a sensation of warmth from the desiccation will usually be the only subjective sensations. Care must be taken to proceed slowly to avoid the development of too nuch heat from the desiccation.

The desiccation is continued until the surface of the lesion appears to be level with or slightly below the surrounding normal skin. There is a shrinking effect which exaggerates the amount of destruction which actually occurs. If the desiccation is carried to the point where the surface of the lesion appears to be level with the skin it will be found that complete destruction of the lesion has not been accomplished, and more treatment is needed. It is often advisable to do this since the final result from this "fractional" destruction of soft moles and fibromas may be no visible scar at all. The interval

between treatments should be two or three weeks so that epithelization is completed before further treatment is given.

After each treatment, a crust forms within a few days. This should be protected and allowed to drop off. In any event, the final scar will usually be smooth and soft. Depending somewhat on the nature of the growth and probably on the amount of destruction attempted at any one time, one sometimes sees a loss of pigment in the treated area. This is thought to occur more often when it is necessary to destroy the entire skin layer and the supporting connective tissue in order to remove the growth.

An attempt has been made to compare the analgesic affect of these acids with carbolic acid and with benzyl alcohol. Carbolic acid compares favorably with trichloracetic acid but is definitely less keratolytic. Benzyl alcohol is less analgesic and has no keratolytic action and is therefore of no practical value for this purpose.

Although the best results have been obtained with the so-called "non-malignant" mole, fibromas and small warts, the method is suitable for almost any lesion which requires desiccation. Other lesions which have been treated with this method are vascular nevi, scar cicatrices,

keratoses and even small "corns." It is possible to curette the lesion after treatment but a reapplication of the acid is necessary before further desiccation is done.

Discussions

Dr. Samuel M. Kaufman, New York City: I have had the pleasure of having read Dr. McLaughlin's paper before this meeting as the doctor has been kind enough to mail me a copy of it beforehand.

After reading the paper carefully, also after having had the privilege of observing Dr. McLaughlin's treatment of such cases at the Skin Department of the Vanderbilt Clinic before and after treatment, I am in a position to state that Dr. McLaughlin has made a valuable contribution to dermatology.

While the use of trichloracetic acid as an analgesic agent on nonmalignant growth is not new, the combination of the use of trichloracetic acid with Oudin current has not been mentioned in the literature, and with its use one is able to minimize the strength of the desiccating current as well as decrease the time of application; the lesions are destroyed with the least irritation and with a good cosmetic result.

While on the subject of the treatment of moles and warts, particularly moles, which usually occur on the face of the fair sex and the reason for their removal is more of a cosmetic nature, I am always faced with two serious problems which I will appreciate if the author of the paper or any other member of the section will be able to en-

lighten me, namely:

(1) How can we, with reasonable safety, judge what type of moles are dangerous and where is the borderline between malignant and nonmalignant type? While I have been fortunate in having removed quite a number of pigmented and nonpigmented moles without any fatalitics, I always stop and hestate before I attempt to remove such

growths.

(2) Tendency to keloid formation which sometimes follows removal of moles or warts either by trichloracetic acid alone or desiccation or by a combination of both. I have met with such cases in the past, but in order to guard myself against such an occurrence, if there is more than one mole to be removed I usually remove the smallest one first and wait some time, to guide myself by the result, before I attempt to remove any others; also by observing the scar formation of the vaccination marks which is usually a clue as to whether or not the patient is subjected to keloids.

Dr. H. D. PARKHURST, *Utica*: I wish to congratulate Dr. McLaughlin on the excellent presentation of his paper at this meeting.

We have been doing this work for nine years, using a Wyeth Endotherm and it has given me a great deal of satisfaction in this work. I have also done a great deal of extensive work in malignant growths and lunus

I differ from the author in the use of the local anesthesia. We have had excellent results in using Abbott's butyn two per cent subcutaneously. As soon as I make my injection I can start desiccation and always complete my work with one treatment. The technic I use is one that I have worked out myself.

I desiccate them with a Bard Parker No. 15 blade and curette away the charred tissue. That allows me to determine if I have carried the desiccation deep enough. A pigmented mole or xanthoma I continue to desiccate until I have gone below the pigmentation.

I think the healing is better to curette away the desiccation and lightly dry the surface with a spark. Treatment: Peroxide, Salve. B.F.I. Powder.

In removing a verruca along the edge of the eyelid, a few drops of butyn injected makes it safe and painless.

Many moles are borderline and I think a complete destruction essential.

We remove the verruca around the finger nails with the same method and it is necessary to do rather extensive work to cure them. The scarring is not bad, also I remove many molluscum contagiousum from the plantar surfaces of the feet. There the deep injection is necessary. Here I use both the cutting current encircling the molluscum and remove it like a small button, then I dry the surface with the spark, then curette to make sure there is a clean base and finish by another light spark to dry the surface. Treatment: Peroxide, Salve, Balsam Peru, B.F.I. Powder.

Since learning about the subject of the paper I have tried the trichloracetic and bichloracetic acid. The first one I tried I thought would be a good test—that of venereal warts. I was obliged to resort to

the local injection. Then thinking that was hardly fair to the treatment I tried it on several moles on the face but I much prefer

the butyn.

The scarring on the face has been very slight and patients repeatedly return for more moles to be removed. If I have any doubt about their scarring I try only one or two, then observe their healing. I find a ruddy complexion heals well with practically no marking.

The cases I am most careful with are the ones with a pasty complexion with no color. I sometimes ask them if they have any scars from injuries or operations then I can determine if they are subject to keloid. If so I follow the treatment with either radium

or x-ray.

I think the senile verruca on the face would be a good condition for the acid applications, but for the deeper conditions such as moles and verucea a local injection should be made, as my patients say that it is painless after the injection.

Dr. R. R. M. McLaughlin: In reply to Dr. Kaufman's question concerning the malignancy of moles, it may be stated that I know of no way of deciding this. It is not my intention to discuss the question of malignancy, but, as pointed out by Dr. Mac-Kee, many years' experience in the removal of the "so-called non-malignant" moles have shown that it is a rather safe procedure. The individual's clinical judgment must be depended upon to determine which moles belong in this class. The question of keloid formation must be considered. One should examine old scars, such as vaccination marks, as Dr. Kaufman suggests, to see if there is any tendency in that direction. If there is such a tendency, almost any method of removal must be considered likely to produce keloid formation. This method is offered as an optional method for the removal of non-malignant moles and not as a substitute for all or any previous methods. Electrolysis is certainly to be recommended in many cases.

DEATH AFTER EYEBROW PLUCKING

An English doctor described the practice of eyebrow plucking as "very dangerous indeed" during an inquest at Birmingham. The inquest was on the body of a hairdresser, who died in Birmingham from streptococcal poisoning. A verdict of "Accidental death" was returned.

It was stated that, two weeks before her death, Miss Amos plucked her eyebrows. A pimple came over one eyebrow. medical treatment, but refused to have the pimple opened, and the infection spread.

Dr. B. T. Rose said that the infection started where the hairs had been plucked. The practice of plucking eyebrows was very dangerous indeed. The case was the second he had dealt with this year, though the other did not have fatal results. Most hair plucking was done without preliminary precautions, but even if the skin and forceps were sterilized it would not be safe.

An attempt is being made at Akely, Minn., to secure a co-operative physician to locate in that village. The idea is that 200 families pay \$10 each a year and in return they will receive the services of a competent physician whenever necessary at no extra cost except that need for medicine and nurses.

Cancer mortality in New York State in 1934 was the highest ever recorded, the State Department of Health reports.

A total of 17,698 persons died of the

disease, a rate of 131.3 deaths per 100,000 of population. This was second only to the mortality from diseases of the heart.

The higher rates for cancer and cardiac ills is attributed to the increasing age of the population by many authorities. is more die of these diseases because fewer die of something else, and men are mortal.

Twenty years ago a man named Balthazar Balmint went to a hospital in London for treatment. It was discovered he was suffering from a rare bone disease which would probably end his life very soon.

The doctors offered to pay the sick man, on condition that he would will his body to them, one pound sterling per month during his life, and to give his heirs seven pounds sterling.

However, Balmint is still living; the hospital continues to pay him an allowance, and this false diagnosis has already cost about 18,000 francs. Naturisme (Paris).

Science reports that there is a possibility of an influenza epidemic in the United States this winter which is founded on the information received by the United States Public Health Service, that there are about five thousand cases of this disease in This epidemic started early in Honolulu. November.

The last big influenza epidemic, that of 1932, is reported to have started in Hawaii. It invaded the United States with a record of ninety thousand cases.

Wholly Unacceptable

The Mandelbaum Health Insurance Act is one of the worst specimens of medical legislation proposed in this state for many years Taken as an indication of what to expect if the practice of healing is transferred to the control of social theorists and politicians, it is another compelling argument against obligatory pre payment for sickness

A basic flaw in most so called social in surance is the difficulty of establishing reliable actuarial estimates of risks and income As S Burton Heath rightly ob serves in a series of articles in the New York World Telegram, '* * * all actu arial computations as to unemployment insurance are feathers in the gale when a depression strikes" This applies with equal force to compulsory health insurance, with its unpredictable drains from epidemics Inaccuracies are multiplied by conjecture when, as in the Mandelbaum Act, wages are assumed to include such mexact items as "the reasonable money value of board, rent, housing, lodging or sımılar advantages"

Flying in the face of experience and reason, the Mandelbaum bill combines cash benefits with medical service Malingering, hypochondria, and destruction of the will to recover are inevitable sequels to this coalition, which sets a premium on illness

This, in turn, charges the profession with the uncongenial and onerous duty of preventing unwarranted raids on the insurance fund The doctor must constantly be on guard against malingering and needlessly protracted complaints Invariably this leads to mistrust on the patient's In the end the physician stands alone between insurer and insured, an object of suspicion to both

Although purporting to preserve the free choice of doctor, the Mandelbaum Act places mordinate powers in the hands of the Health Insurance Board This body need not necessarily have a physician among its members, only one of whom "shall be representative of the professions engaged in furnishing the medical benefits", but it has the right to remove practitioners from the approved lists and to erect new hospitals, laboratories, and clinics at its discretion

The whole executive structure of the proposed system is top heavy, entailing an elaborate and expensive bureaucracy in which administrative considerations appear to overshadow the primary question of high grade medical care Naturally the upkeep of this bureaucracy is a first lien on monies collected A vast army of directors, board members, supervisors, managers, clerks, stenographers, inspectors, etc. must be paid before funds are available for medical care—the basic purpose of the law-and the promised cash benefits.

The public should not be deceived into believing that compulsory health insurance is paid for by the limited group that benefits. The contributions from the government and industry are passed on to the entire consuming public in the form of higher taxes and increased prices, so that the whole community pays for dubious benefits to a special class.

In the Mandelbaum Act the evils inherent in compulsory health insurance are enhanced by poor judgment and a total incomprehension of the essential nature of the problem of medical care. This dangerous sample of half-baked politico-social reform should be repudiated so conclusively as to preclude further attempts along the same lines.

A Faulty Comparison

A large New York daily recently headed an article on the amended Workmen's Compensation Act with a caption proclaiming that medical fees may lift the cost of this type of insurance. The unnamed author of the article in question appears deeply concerned with the fact that some of the fees in the State Society's proposed schedule are higher than the old charges; but apparently he has made no effort to compare the suggested schedule with prevailing fees or to investigate the low grade of service under the old rates which prompted a change.

The entire article is a jumble of misunderstanding and misinterpretation. Apparently without knowledge of the restrictions in force, the author complains that "every physician, surgeon and specialist licensed to practice in New York State is entitled to membership on the panel"; that, "instead of becoming a 'blue ribbon' panel, it has become wide open," with 14,000 names on it already, "as contrasted with perhaps 2,500 medical men, selected with care, who had most of the compensation practice heretofore."

It is hard to reconcile the author's

desire for a "blue ribbon panel" with his apparent belief that fifty dollars is excessive for two months treatment of a closed carpal fracture and one hundred and seventy-five dollars excessive for the reduction and subsequent care of an open fracture of the femur. It is not the rule in any profession for low paid work to attract the most eminent practitioners.

Inasmuch as a licensed physician is authorized to treat any and all diseases and deformities of the human body, it would not be as startling as our anonymous critic appears to think if compensation work were open to the entire profession. In fact, however, practitioners must present evidence of their experience before they are accepted and the scope of their participation in compensation work is restricted according to their qualifications. The result so far has been definitely better than when this field was limited to a small group of physicians who, far from being selected with care, were recruited principally from the inexperienced, the incompetent, and the politically connected.

The article under discussion shows so little understanding of the medical aspects of workmen's compensation that it would not deserve mention if it were not for the fact that it appeared in an influential newspaper and similar misconceptions may be widely held. The incident suggests that the profession should clarify its position before the public to prevent interference with its program because of misinformation.

Physical Education Directed by Layman

When the position of Director of the Department of Health and Physical Education in the State Department of Education was about to be filled, there were many among us who were astonished to learn that affairs were so shaping themselves that the appointment would be made of a layman to carry on this particular type of work. The matter received attention by our Executive Committee and by the President of our Society.

Eventually the appointment was made, and a layman received the 10b

Here we have a situation which should not be permitted to recur It would seem to the least thoughtful among us that he who would teach health and physical education, and direct the activities of such a department should be well grounded in the fundamentals of biology and chemis try, as well as those of matomy and pathology, including bacteriology. In no course could so good an education be acquired in these subjects, as in the medical curriculum, while studying for the degree of doctor of medicine It should be a fundamental concept that he who would direct and teach matters concerned with health should be a doctor of medicine

In this connection, and relating to the issues raised in our Executive Committee by the facts, we publish elsewhere in our columns (see page 364) the report of Dr Arthur Bedell, chairman of a committee appointed by the President to report on the facts concerned in the recent appointment which was so disappointing to organized medicine in this State The report should be read by all

The simple, outstanding fact which the report denotes, is that the examination was oral, and the appointment was made upon the finding of one examiner only. The only one to please this examiner who, by the way, was Dr. Jesse F. Williams, head of the Department of Physical Education of Teachers College, Columbia University, was Mr. Hiram A. Jones, who was appointed.

Protests were made by the New York State Santary Officer's Association, the New York State School Physicians Association, the State Health and Physical Education Association, and the New York Teachers Association Our own Public Relations Committee under the leadership of Dr Warren also made contact with the State Commissioner of Education to no avail Everyone is out of step but Johnny!

There is a record of the attitude of mind of Dr Williams which hardly would commend him as mentally equipped to evaluate medical men While the record also discloses a teacher student relationship between examiner and successful candidate, it also seems to show the inherent dangers in any system of competitive examinations in which the determining factors are left entirely in the hands of one man

We would not be warranted in assuming more than is implied in the open record. That this in itself leaves much to be desired is unquestioned. The prestige and the reputation of the whole civil service is just as weak as its poorest element. The integrity of examiners and examinations should be beyond suspicion. Obviously a teacher should not qualify his own student, and certainly to leave it a one man job is putting a premium upon suspicion.

It is earnestly hoped that the Civil Service Reform Association will take cognizance of this case, and investigate it to the end that a repetition of such a procedure will be made impossible

Why Not Cooperate?

There has lately grown up in our communities bad feeling and ill will between practicing physicians and the hospitals. This state of affairs has not been lessened by the "publicity blast" carried in the current news columns of February 17, 1936.

James U Norris president of the Hospital Association of New York, issued a vigorous protest against recent rulings under the State's workmen's compensation law which deny the hospitals the right to charge fees in the treatment of compensation patients for the use of the hospital's own facilities Mr Norris de clares that because the hospital as such has been equipped with x ray machines, and has acquired expensive apparatus to deliver physiotherapy, therefore, the lospital has an inherent right to collect fees for using these facilities on compensation patients

We are aware of the financial predica-

ment in which most of the voluntary hospitals find themselves, and we can comprehend the lure which these fees hold to the exhausted exchequers of the hospitals. Likewise, however, we are cognizant of the facts which resulted in some of the newer amendments of the workmen's compensation law. Some were made necessary because fees were charged and were collected by hospitals for treatments delivered to compensation patients, while the physicians who were responsible for the medical treatments and administered them, were left holding an empty bag!

There would seem to be less need for vigorous protests publicly made which tell only a part of the story, than for peaceful, calm conferences to find that just and true middle ground which actually makes the doctor's services and the care delivered by hospitals complements of each other.

Because the hospital has invested money in x-ray equipment and in expensive physiotherapy apparatus gives it no more logical reason to deprive the roentgenologist and the physiotherapist of the fees they legally earn when treating compensation patients and using such apparatus, than it permits the hospital to collect and keep the surgeon's fees because while performing necessary surgery on the same group of patients he uses sundry hospital apparatus and the hospital operating table.

The hospital rightly, as a corporate body, should be permitted to charge only for domiciliary care. In estimating the charges for such care, the overhead costs, and the use of all apparatus may well be reckoned into the accounting.

Why a publicity blast? Why stress differences, when calm council can bring mutual understanding? The Hospital Association of New York could do better by itself through meeting the profession and working toward, and stressing common ground. Surely there are no two other organized groups from whom so much could be accomplished when they will have learned to work together. Why

The Clinical Day

It is not often that one feature of a convention meeting can be made to appeal to every visiting physician. In the "Clinical Day" which the committee under the chairmanship of Dr. Charles Gordon Heyd is providing there is something for everyone visiting the city during our State meeting. Even for the profession at home in the city there is afforded an opportunity not often used, to visit sister institutions and see colleagues at work.

The local profession in the metropolis is justly proud of its great universities and their fine medical colleges, and also has pride in the distinction of its many independent teaching hospitals and clinics.

Here the seeker after medical knowledge will find anything he needs and wants. Every type of specialty and every type of laboratory is to be found in the convention city this year. Most of the great clinicians, whether on the general program or not, will be found at their posts, ready to demonstrate and show clinical material.

With the least amount of formality, there is available both the expert and his work to answer the problem which is confronting your practice. Use this opportunity, seek him out who can give you something to clarify your problems. Showmanship for itself will not be stressed, but practical, useful methods of diagnosis and therapy, both surgical and nonsurgical, will be "on parade." No tickets for admission are needed. If you know of a man working in a line in which you are interested, you will have little trouble finding him.

Make reservation of your time wisely. Much will be offered, and you will need to award your time wisely to meet your individual needs. The demonstrator is less interested in having a large audience, than in having a group of physicians interested in this kind of study.

We venture the prediction that you will agree that New York City's hospitals and clinics will give you in one day some-

thing in which all your time may be wisely invested. It is the hope of those in charge that both patients and the profession alike will benefit from the interchange of clinical experiences.

The Social Functions of the Annual Meeting

We seem to stress our problems It is necessary that we keep before ourselves the serious duties which we are called upon to carry out Nevertheless the old adage that all work makes Jack a dull boy is never truer than among those of us who work year in and out, and during all seasons, carrying on the society business and its affairs

We have issued an invitation for all to come and observe your elected delegates at work. Your presence will denote your interest and help by showing your accord and appreciation for much devoted service. Learn to know by sight and name those whom you have entrusted with the mandate of leadership.

Nowhere, as in a social gathering can the qualities of a man be evaluated. When "off-guard," and in informal talk, clarity of confused ideas is often more easily possible than during the formalities of parliamentary debate. In the social sessions, during which men meet and learn to know one another, is born that confidence which permits your officials and committee-men to carry on the numerous tasks you assign to them.

The banquet on the evening of the second day is the culmination of the social activities. This year, as we have already stated, the number of available tickets will be strictly limited. Reservations should be made promptly. We shall note details more fully in our next issue. Today suffice it to issue this reminder.

Silicosis

The study of silicosis as an occupational disease has been carried on intensively for the past twenty-five years. Workers in sand blasting, hard rock mining, and granite cutting present those mostly

afflicted It occurs also among the workers in metal grinding industries, as well as among those who are compelled to work in an atmosphere laden with dust particles containing free silica

The disease itself is essentially a fibrosis of the lungs, eventually causing dyspiea, cough, and pain in the chest. Frequently, after a lapse of time, pulmonary tuberculosis develops

In a study of 208 rock drillers, blasters and excavators in New York City, 118 or 57 per cent were found to have silicosis. An investigation by a subcommittee of the House Labor Committee presented evidence which placed the number of deaths from silicosis during the construction of the tunnel from New River to Gauley Junction as having been from 200 to 476.2

Only eleven states have legislation which provides protection for the workmen in industries in which they are subject to silicosis, and gives these workers compensation for the hazards to which they are exposed

Concerning protection against silicosis, there does not seem to be any one sure method that meets the working situation under which these men labor, and gives them satisfactory protection. Until an effective protective means has been devised and perfected, any and all manner of means which will help in diminishing the concentration of dust should be used to safeguard the laborers.

In regard to workmen's compensation regulations regarding these silicosis sufferers it should be recognized that silicosis is an industrial, occupational disease and that late complications are prone to happen. We now realize that silicosis has a prolonged period of latency. Once diagnosed as clinically evident, it is very apt to become a chronic ailment. Standards for diagnosis are not well established, and studies toward this end are needed. Furthermore, a classification of the degree of injury and incapacity is necessary

¹ Smuth Adelaide Ross Journal Industrial Hy giene 40 2 1929 2 Tucker, R N Y Times Sec. 4, page 7, February 16, 1936

Meanwhile, in justice to the workmen, pending some solution of the silicosis problem, this disease should be considered a compensable disease; and because of the late appearance of the complications, the case should not be closed at the initial stage of the pulmonary involvement. The ordinary rules of administering workmen's compensation need revision as regards this affliction. Sufferers from silicosis should not be denied compensation for their malady, or deprived of the right to seek it, because of the lapse of time between which they were exposed to the hazard, and the time when the late pulmonary lesions develop, and its symptomatology is manifest. It requires expert knowledge of silicosis and its complications and considerable experience with such cases, to enable one to make both diagnosis and prognosis.

Organized medicine can help labor by fostering corrective legislation, not only to safeguard the workers, but also to develop the medical administrative data so as to compensate those who must meet the hazards of silicosis.

Spinal Anesthesia

There is no means of producing surgical anesthesia with such a profound relaxation, particularly in the field of abdominal surgery, as that obtained by the use of spinal anesthesia. For this reason many abdominal surgeons have almost totally abandoned other methods of administering anesthesia in favor of the subarachnoid injection of cocaine derivatives. It is true enough that in the largest number of cases wherein spinal anesthesia was employed no ill effects have been noted; yet neurologic disturbances have been noted, and recorded.1-8 Among such reported observations are cranial nerve palsies, myelitis, lesions of the cauda equina and meningoencephalitis. Brock, Bell, and Davison 4 report two cases of aseptic meningitis, one case of polioenceph-

alitis; two cases of cauda equina neuritis; one case of lumbar radiculitis, and one of transverse myelitis. All these followed spinal anesthesia induced by nupercaine, Jones solution, procaine, etc.

It is known that spinal anesthesia has produced degenerative changes in the spinal cord, disintegration of the axones, and degeneration of the peripheral portions of the cord. In some instances these effects are attributable to chemotoxic reactions. Not all patients are prone to such tissue reactions however, although some undoubtedly are. It is thought that chemotoxic reactions account only for some of the bad after-effects noted, and it is surmised that there are probably other factors which play an etiologic role in the production of the lesions noted above.

Brock and his associates believe that certain individuals are possessed of a nervous system whose tissue is particularly sensitive to the cocaine derivatives. At the present stage of our knowledge, there exists no way to determine in a given case, the presence or absence of this sensitivity. Furthermore, once nervous complications have appeared, we are handicapped by the lack of any effective therapy to combat the development of the neural lesion.

From these observations, we are forced to conclude that except for the more profound abdominal relaxation obtained by the surgeon, he increases the surgical risk in his case when he uses spinal anesthesia rather than diminishes it. No surgeon employing spinal anesthesia can be sure that later in the case-history of the patient neurologic disturbances will not appear.

We are induced to comment on this because of the trend in surgical practice to utilize spinal anesthesia as a routine measure, and by drawing attention to the reports of competent observers, warn of its dangers. Brock urges, and he is supported by E. D. Friedman, that Hyslop's dictum should be our guide; to wit, "Spinal anesthesia should be restricted to a special group of individuals unable to withstand the risks of a general anesthe-

CURRENT COMMENT

THE ASSOCIATED PRESS reports from Albany, under date of February 17 in the New York Sun, that New York's health conditions at the beginning of this year were the best in many years. This is according to reports made by the State Department of Health. The exception is to be found in cancer. The death rate, 10.8 per thousand of population is the lowest in a half century. Infant and maternity mortality was the lowest in history. Deaths from appendicitis, suicide, homicide, alcoholism, and automobile accident death rates were also exceptionally low. Dr. J. V. De Porte, the director of the division of vital statistics states that the cancer death rate had risen to "the highest level so far experienced."

From Medical Economics of February, 1936, we find an interesting article by J. Weston Walch who is general manager of the Debaters Information Bureau of Portland. Maine: and also is compiler of the Handbook on State Medicine. He writes an article in which he says, "I don't want to be a statistic! Statictics have no feelings! * * * I rebel at becoming an impersonal number. When I have a stomach ache it is my ache. It hurts me, * * * I am not interested in the fact that 79% of the American people should go to a dentist. I have got to go to a dentist. * * * When I am very sick, I am very unreasonable. * * * I want the best doctor regardless of whether my ailment is a little one or a big one. That is the one time that I insist on efficient service. * * * (1) Would state medicine provide me with the best of doctors? (2) Would those doctors have modern equipment? (3) Would they be interested in me and my welfare? (4) Would they treat me quickly and efficiently? * * I have seen too many politicians spending too much money to get into public office to believe that many of them are honest. I wouldn't accept the advice of one of them in betting on a horse race or a prize fight, let alone in picking a doctor to operate on

I have so often heard the free school system compared with our medical system that I immediately think of our present school equipment in connection with state medicine. The economics classes in the biggest high school in my own city are studying from a textbook which teaches that the Federal Reserve System put an end to all depressions! You can imagine when that book was written! I wouldn't want a doctor with equipment that antique. And I'm afraid that's what my state would give me!

The same politicians who would be able

to force an inferior surgeon into the hospital system in my community would also control the funds which would go to operate the system. I fear that the order for ether, or bandages, or vaccine, would not be approved until the right politicians had received their little rebates. * * * Would these doctors be interested in ME and my welfare? It is a bit difficult for an efficiency expert to see why I want my doctor to be interested in MY troubles and not be satisfied to have him make a mere scientific attack on the malady with which I am afflicted. This is difficult for any one to appreciate when he is well and the problems of sickness seem remote. I must ask you to try to imagine how state medicine would work when you are seriously ill-when the things of time and sense in your everyday world recede and leave you isolated to face the forces of disease. * * * You are patient number 196 in ward 112. You were sen there by doctor D-19 and examined by intern number I-42 preliminary to opera-tion by surgeon S-76. The surgeon does not have to come to see you. He can learn all about you-your past medical history and present complication-by consulting his card index. You are merely a part of his day's work. Besides, he has other patients a lot sicker than you are. As you lay there you wonder how many of those patients got that way through neglect under the "free" state system. And that helps neither your peace of mind nor your recovery.

The efficiency experts may be satisfied with the marvelous statistics that the state medical systems will keep, covering the records of each patient. But as for me, I don't want to classified. I want to be cured!

* * * Under a state system, if a doctor told a patient that he didn't need any pills and treatments, he would be suspected of loafing on the job. If he prescribed treatment distasteful to the patient, or if the patient regarded it as inadequate, he would run the chance of being reported to the management, like an impudent hotel bell-

hop!"

From the Health News of February 17, 1936, issued by the State Department of Health at Albany, New York we read that: "Expenditures in 1935 for medical care of the needy unemployed on relief in New York State totaled \$3,340,000, more than two per cent of all home relief expenditures according to a recent report by H. Jackson Davis, M.D., director of medical care for the State Temporary Emergency Relief Administration, and assistant director of local health administration, State Department of Health.

After five years of business depression

358

and unemployment, Doctor Davis points out, the general public health in New York State has never been better than it is today. Medical authorities are agreed that proper medical care of the great group on relief -which has included one-sixth of our population and one-quarter of all the children in the State-has been of paramount importance in the continued health of the whole community.

The expenditure of this money for medical care of those on home relief was an integral part of the relief given under the terms of the Wicks Act by which the State of New York recognized medical care as a necessity of life along with food, clothing,

and shelter.

Since the TERA has insisted that the money should be expended for the purpose of supplementing rather than supplanting existing facilities, a large part has provided medical services to the needy in rural districts. This means, not that the rural communities received more than their share of relief moneys, but that, lacking extensive public medical facilities, they spent a larger portion of the money to provide needed medical care while in New York City, for instance, where the hospital and out-patient facilities were numerous, such money went for food and shelter."

WE QUOTE AGAIN from Medical Economics "A questionnaire was of February, 1936. sent recently by the state medical association of California to all its members, asking their views in regard to bills which would make health insurance compulsory. Late reports have it that the replies to date from California physicians are 63 per cent against the association endorsing legislation to change the status quo of medical practice; 76 per cent against compulsory health insurance; and about 58 per cent for voluntary health

Dr. WILLIAM H. HOLMES, Associate Professor of Medicine of Northwestern University Medical School, says: "The general public has little realization of the tremendous amount of effort expended annually by individual physicians and by organized medicine in combating pernicious legislative measures, sponsored by misguided enthusiasts and by those with ulterior motives. There isn't a legislature in America which does not annually have bills presented for consideration which would, if enacted, destroy health pro-Bills to lower the standards of medical education to force the recognition of untrained cultists by health boards and hospitals, to prohibit animal experimentation, are common dangers which must be fought constantly. The opposition of medicine to such measures is based on its obligation to protect the public health, and to protect scientific and clinical investigation into the nature of disease.

In its opposition to measures that threaten the public welfare medicine employs no lobby; it makes no threats; it offers no political support. To accomplish its purpose, it must depend in the future as it has in the past, on the influence of enlightened public opinion. American facilities for medical care are unsurpassed but much remains to be accomplished before the ideals of medicine are realized. In their realization, society has obligations no less than those of medicine." -From the Supplement to the Bulletin of the Medical Society of the County of Queens, January, 1936.

THE Health News of February 3, 1936, carries the announcement of the retirement of Dr. Hugh S. Cumming as surgeon general of the United States Public Health Service on February 1st. "Doctor Cumming entered the Public Health Service in 1894. In 1920 he was appointed surgeon general, and at the time of his retirement was nearing completion of his fourth consecutive term in that capacity.

His administration is credited with the establishment of the National Institute of Health, the completion of the national quarantine system, inauguration of preimmigration examinations at American consulates, establishment of a national leprosarium and national narcotic farms, and construction of eight marine hospitals. He has figured prominently in the promotion of international health activity as vice-president of the Health Section, League of Nations; American member of the Office Internationale d'Hygiene Publique; United States representative and signer at the Pan American Sanitary Convention, Havana; director of the Pan American Sanitary Bureau; and president of the Allied Medical Mission to Poland."

EDITORIALLY, Medical Record carries the following in its issue of February 5, 1936.-"Next to politics, is there a more popular subject in the lay journals than medicine? Pick up any magazine at any time, and there will be at least one article dealing with a medical theme. Everyone is writing on medical economics, saving the doctor from or helping him into some form a socialized medicine. New discoveries or near-discoveries are popularized. Medical memoirs, experiences of patients, phases of medical history, the whys and hows of bodily behavior, the ways of bacteria and cancer and the liver, and countless health matters are

rephrased in popular terms for the tremendous magazine-reading public. Some of the articles are of passing interest, some are of negligible value, and some are important. Occasionally one appears that the doctor cannot afford to miss."

THE Westchester Medical Bulletin of February, 1936, carries the following editorial which is so enlightening that we are publishing it in full. "The Bulletin of the publishing it in full. American Medical Association for October, 1935, contains a reprint from the Journal of the British Medical Association of an article by Dr. McI. Johnson, M.B., B.Ch., who, besides being a practicing physician is a barrister-at-law. This paper, entitled A Case Against the Extension of Public Medical Services, cuts through the maze of sentimental irrelevancies which befog most discussions, both pro and con, on the subject of State Medicine, and lays a precise finger upon the basic issue with respect to which anyone who takes sides in this question must ultimately be prepared to state his position.

What is this "basic issue?" Let us approach it by considering these passages quoted by Dr. Johnson from a recent book by Lord Hewart, the present Lord Chief Justice of England, entitled The New

Despotism:

"In the kind of "legislation" which is being considered, it is usual to provide that the decision of the Minister shall be final and conclusive. When this is the case, the courts are powerless to intervene, however unjust and absurd a decision may appear to be . . It may be said that there is no substantial ground for the fear of unfairness or corruption in the Civil Service. . . . But if there were any great extension of the system of giving uncontrolled and arbitrary powers to public officials, it is as certain as that night follows day that corruption might creep in. We might then be cursed with the corrupt bureaucrat. The bureaucratic despot we already have. To take a simple instance, the treatment of the panel doctors under the National Health Insurance Acts is pure despotism. The doctors are liable, at the mere discretion of the official who acts for the Minister of Health, to be ruined professionally by being struck off the panel, or, as a lesser punishment, to be fined to an arbitrary extent.'

"Thus it is the considered opinion of the Lord Chief Justice of England that the treatment of the physicians under the vaunted British Health Insurance system is pure bureaucratic despotism and further, while he finds no present evidence of political corruption in the system, Lord Hewart warns that

as increasing powers are given the civil administrators of the system, the contamination of corruption will follow as night the day.

"'These paragraphs (and in fact, the whole book), asserts Dr. Johnson, should be read by every doctor practicing or in-tending to practice under the panel. They should be hung, like the landladies' texts of our student days, by the bedsides of all those who frame the policy of the medical profession. We should be aware of the dangers of our position as pointed out by the highest judicial authority in the country. Lord Hewart clearly demonstrates how our rights as individuals can be stolen away by a few words insidiously inserted here and there into Acts of Parliament: "The Minister's decision shall be final," "to determine as the Minister shall think fit," etc., can abrogate rights gained and retained through centuries of struggle, and hand us over to the arbitrary jurisdiction of minor civil servants. Yet we doctors hasten to throw ourselves under the wheels of this juggernaut. the Ministry of Health in unfriendly hands. the slender protection of medical service subcommittees could quickly be abolished; should we not awake before the "Divine Right of Insurance Clerks" receives its final affirmation?'

"In another passage, Dr. Johnson warns that: 'Should it (the administration of the system) fall into inefficient or inimical hands it has, in its present form, endless unfavorable possibilities. There is a certain distastefulness about "complaints to the insurance committee"; there shows itself, even now, the inevitable tendency of the bureaucrat to tyrannize over petty matters, and an accompanying tendency to back the patient up against the doctor; and there is, worst of all, the absence of any right of appeal to the courts of law from the decisions of the "Minister" (which means, of course, an official in the Ministry of Health)-the complete denial or our right to ordinary English justice.'

"Now if the American physician were to submit himself to a program of compulsory state health insurance, who can doubt the inevitability of political corruption from the very start? Lord Hewart finds 'no substantial ground for the fear of corruption in the (British) Civil Service.' But, unfortunately, as every school boy in America knows, to mention the American Civil Service in the same breath with that of England is to confer a gross libel upon the English Civil Service System.

The whole tradition of civil service in America—aside from a few notable areas in the lower ranks of certain public services—rests upon the thesis that government appointments are properly the plums of political spoilsmen. An illuminating commentary on this condition is found in an article by Mr. Kenneth Coolbaugh under the title 'Public Servant,' which appeared in Nation's Business for December, 1935.

Rightly or wrongly, the American profoundly distrusts the integrity and efficiency of the public service. At the same time he fears instinctively that any enlargement of the civil authority inevitably means a curtailment of civil liberties. As applied to the investment of social control over great monopolistic accretions of industry, this popular mistrust is perhaps mistaken and regretable,—but when the issue is the intrusion of bureaucratic absolutism into the realms of the sciences, arts, and individualistic services,—our antipathy to governmental control rests on a sound bedrock of wisdom.

The American physician knows, deeply and intuitively that State compulsory health insurance in the United States could not be anything but a disgustingly corrupt, expensive, despotic, inefficient juggernaut, debasing the incentives, the ideals, and the character of both the practitioners and the practice of medicine, and his experience with the emergency programs of state medicine that have been forced on him in the past several years have confirmed his worst fears in this respect.

But the issue of the socialization of medicine involves a larger public question even than the fate of modern scientific medicine. If the public endorses state medicine, it must expect coincidentally to face the general question of political bureaucratic despotism . . . under what has been historically and traditionally the most corrupt public service in any democratic nation."

"JUST AS MANY CITIZENS are prone to look upon their local government as unimportant, so there are physicians who accord the county medical society an insignificant role in organized medicine. Of course, this

is all wrong. Corrupt and inefficient local units of government can undermine a national administration to such an extent that the very life of the country may be endangered. And so with our county medical societies; unless they are strong and well-organized, obviously, the national organization will suffer.

Recognizing this important fact it is essential that county medical societies be more than mere organizations in name. It is incumbent upon their officers to determine how adequately they are meeting their responsibilities, for it seems apparent that if local problems are adequately met national issues will in a large measure take care of themselves. * *

How effectually the county medical society meets its obligations does not depend as much on leadership of officers as some physicians would like to believe. Harmony, understanding, and unanimity of opinion on vital matters, however, must exist among the majority of physicians. Where such spirit is in evidence much worthwhile progress can be expected even though leadership may not be all that might be desired.

There has been much written about medical society plans which would solve some of the economic problems that confront patient and physician. These plans, whatever their merit, are certainly not adaptable to all communities, and yet we see a tendency among some medical societies to try to fit the community to these plans rather than to adapt what is worthwhile in them to conditions existing in the community. Such efforts can result only in failure and they emphasize the point we wish to make, that a thoughtfully guided and progressive county medical society will, through its officers, study its local situation carefully and sponsor only such measures as seem vitally necessary and desirable for the health and protection of the people."—From the Supplement to the Bulletin of the Medical Society of the County of Queens, in its February, 1936 issue.

The ordinary cup of tea contains only a grain or two of caffeine, but it has a considerable amount of tannin, the amount depending upon the kind of tea and the mode of preparation. Milk added to tea completely nullifies the effect of the tannin.

—Journal of the Canadian Medical Association.

Surgery of the skull known as trephining is by no means modern. It is known to have

been practised 10,000 years ago in Europe, but, strangely enough, it was also known to the Peruvians, and now evidences have been found in Alaska of its use 2,000 years ago among Indians whose skeletons recently have been found.

Court reports in an upstate newspaper tell of a young doctor who sued his grandfather for \$150 for attending his grandmother in her last illness.

COMMITTEE OF REVISION
OF THE

PHARMACOPOFIA OF THE UNITED STATES OF AMERICA

1930-1940

43rd St. and Woodland Ave. Philadelphia, Pa.

To the Editor:

A copy of the address given in New York City before the New York Branch of the American Pharmaceutical Association, on January 13, 1936, is enclosed. (Address in full given below.)

This outlines the developing Pharmacopocial program, especially "interim revisions" and the program for extending information to physicians concerning the use of official medicines.

It is hoped that these statements will be widely publicized as they should be of interest to every manufacturing and retail

pharmacist.

E. FULLERTON COOK

A PHARMACOPOEIA FOR TODAY'S NEEDS

E. Fullerton Cook

Chairman of the U. S. P. XI Committee of Revision

An Efficient Medicine for Every Therapeutic Need. About a generation ago a new
therapeutic era was ushered in under the
stimulus of a group of earnest clinicians
and pharmacologists who were greatly influenced by the relatively new evidences of
drug action or inaction, through animal
experimentation.

By some critics this group were termed "therapeutic nihilists" since they questioned the value of most drugs in the prevention or treatment of disease. One prominent clinician believed that only about a half dozen drugs were worthy of consideration since their physiologic activity could be demonstrated chemically or biologically.

Under the brilliant and able leadership of Dr. Osler the chairs of therapeutics were driven from most of the medical colleges and it has taken years to return to a reasonable and sound restoration of this important branch of medicine.

This process was revolutionary in nature and like all revolutions the proponents swung far to the left, questioning all traditions and empericisms. Again history repeats itself and medicine is rediscovering the importance of "therapeutics" but basing this acceptance upon clinical evidence and scientific proof.

Tremendous advances have been made in the efficiency and specific character of many medicines during this period; and the thousands of trained investigations in colleges and universities, in heavily-endowed medical research institutions and in the research laboratories of a few of our pharmaceutical and chemical manufacturing firms, give much promise for the future.

During this revolutionary period the Pharmacopoeia has kept pace with every development and the Eleventh Revision represents the clear cut policy of its founder, Dr. Spalding, who, in 1820, stated that a Pharmacopoeia to properly function must recognize the important medicines of its day. Unfortunately a few important medicines are excluded from the U.S.P. XI by the unwillingness of patentees to have their products included. Insulin and pentobarbital are in this group. It has been the policy of the present Committee of Revision to include a medicine for every therapeutic need when such is available.

The New National Formulary contains

The New National Formulary contains preparations and standards for a number of these U. S. P. medicinal substances, especially as tablets or in parenteral solutions, or in nasal and throat preparations and elixirs.

The U. S. P. has taken the theoretical position that it should supply efficient therapeutic agents in such simple form that the physician could combine them in an original prescription to meet the needs of each patient.

In practice, however, the physician often finds it advantageous to use a form of combination prepared by skilled pharmacists, preparations having the correct proportion of medication and suitably flavored For all such needs there should be an official preparation either in the U. S. P. or N. F. and the new revisions of both books are approaching this ideal.

Medicines of Superior and Uniform Quality and Potency. The letters "U. S. P." on a label should mean to physicians, pharmacists and the public a superior quality, one

adequate for every therapeutic need. An honest effort has been made to fix the standards of the Pharmacopoeia so that a maximum of efficiency will always be obtained yet without the unnecessary cost due to the exclusion of the last traces of harmless foreign substances.

Furthermore a reasonable range must be permitted in U. S. P. standards to allow for the slight differences in analytical results obtained by even well-trained chemists and also because some deterioration is likely to occur even under the best storage conditions.

Scientifically Correct and Usable Titles. Some official titles have been criticized because of their cumbersome character and it must be admitted that it is difficult to learn even to pronounce such titles Erythrityl Tetranitrate but this is scientifically correct and had already been adopted by the British Pharmacopoeia, and thus adds to the U.S. P. and B. P. uniformity. This has been a mutual policy for ten years.

In practice the Pharmacopoeia has proabbreviations vided official and synonyms for use by physicians in prescribing, and there are advantages in the use of these which many physicians are recognizing. When titles are too short, euphonious and catchy, especially when they call for trade marked and packaged medicines, the patient usually reads the prescriptions, buys it at a cut price store, and then, if it has been efficient, recommends it to friends. This is not usually in the best interest of the health of the patients or the friends who thereafter are likely to dose themselves with that medicine indefinitely and unwisely. Physicians should learn—and use—official abbreviations when ordering medicines.

Efficient and Useful Vehicles. A wide variety of pleasantly flavored vehicles with different solvent properties are provided in the U. S. P. and N. F. Pharmacists should carry samples of these to physician friends and demonstrate their application. The various ointment vehicles and their specific

uses should also be explained.

Research by Outstanding Scientists, both National and International. The independent and scientific position of the U.S. Pharmacopoeia has always enabled it to command cooperation scientific workers the of

throughout the country.

This feature has been greatly intensified during the past five years and the program now under way offers opportunities and insures results of far-reaching importance. Happily much of this is assuming international importance through the participation of the pharmacopoeial commissions of other nations. The studies now under way deal with vitamins and anti-anemia products,

these two being under the direction of special Pharmacopoeial Advisory Boards consisting of internationally known experts.

Another study deals with digitalis. This will be by clinicians and biological experts and will continue for several years. The help of the British Pharmacopoeial Committee, the Swiss Pharmacopoeial Commission, and the Canadian experts is assured. Other studies dealing with pepsin standards and assay, aconite and ergot assays, soaps and antisceptic solutions, ointment vehicles, the extraction of drugs and the preservation of drugs and chemicals are among the researches under way.

Undclayed Revision of Standards by Interim Revisions Whether Necessitated by Scientific Advance. Although authorized by the Pharmacopoeial Conventions since 1900. the Committee of Revision rarely took advantage of the opportunity to revise the official standards between revisions. The wisdom and actual necessity for such revisions was faced by the Committee several years ago and promptly accepted as an essential policy for a Pharmacopoeia which was to meet the needs of today with its rapidly developing sciences. Four such "Interim Revisions" were released from 1933 to 1935, providing new standards for Cod Liver Oil, Ergot, Lactose, Oil of Lemon, Magnesia Magma, Bichloride Tablets and Non-destearinated Cod Liver Oil.

This policy has fully demonstrated its importance and with many new researches now actively in progress under Pharmacopoeial supervision, with new facts being announced almost daily by the investigators in these related medical sciences, and with valuable new therapeutic agents being developed, the Pharmacopoeia must of necessity adopt the plan of interim revision announcements. It is hoped that official announcements may be made from time to time as revisions or additions are decided by the Committee but that the printed text may take the form of an "Annual Supplement Pharmacopoeia," appearing the January first of each year.

This plan would largely overcome the difficulty of securing publicity to changes, for the users of the Pharmacopoeia would soon learn to expect a supplement yearly and would naturally consult the original Pharmacopoeia and all of its supplements to determine the actual standards in force.

Prompt Recognition of New Medicinal Agents Whenever their Merit has been proven. The U. S. P. Convention also authorizes the acceptance of additions to the Pharmacopoeia whenever, in the opinion of the Committee, the value of a new remedy justified such recognition.

It is not expected that this permission will be taken advantage of very frequently for a medicinal product is not admitted to the Pharmacopocia until its importance has been widely recognized by the medical profession.

Products such as Insulin, unavailable until 1942 because of patent control, will undoubtedly be admitted as soon as the patent

expires.

A serious problem for future Pharmacopocial Committees will be the complications arising from the increasing tendency for universities and manufacturing firms to patent or trade mark new medicinal products.

The policy followed by the Committee up to this time has been the inclusion of meritorious new therapeutic agents of the patented or trade marked class, only when the consent of the patentee or controlling factor had been obtained. When a product was controlled by and its distribution limited to one firm, even though consent to include in the U. S. P. had been granted, it was believed unwise to admit such substances.

This situation must be restudied and, if possible, some way devised whereby essential new medicines may receive Pharmacopeial recognition even though patented, otherwise the basic principle of the Pharmacopoeia cannot be maintained namely that "it shall include the important therapeutic medicines

of its day."

It was never intended that the inclusion of a product in the U. S. P. should in any way alter the legal rights granted an owner under patent or trade mark laws.

An Organized Program for Extending Reliable Information to the Medical Profession Concerning the use of Official Medicines.

A-Articles by Eminent Clinicians Suggesting Treatment for Specific Diseases. Through coperation with the officials of the American Medical Association, one article of a series of twenty-four, will appear every two weeks for a year in the Journal of the A. M. A. These will deal with the use of official medicines in the treatment of disease and will be written by leading medical men specially qualified for he presentation of each subject. The series will be subsequently published in one volume for the information of medical students, medical and surgical internes, and for physicians in practice.

Special Articles will be presented on prescription writing and the use of official vehicles and typical prescriptions will be included.

typical prescriptions will be included.

B—Suggestions and Helps for Hospital
Pharmacists and Pharmacists in General Practice in Extending Information to Physicians
Concerning the Use of Official Medicines. A
corresponding series of 24 articles will appear
in pharmaceutical journals some weeks prior
to the medical articles so that pharmacists
and pharmaceutical manufacturers may empha-

size to physicians the official products to be discussed and recommended in the forthcoming A. M. A. Journal articles. Pharmacists could even fill some of the typical prescriptions and show them to physician friends as an aid to them in prescription writing. This will be appreciated especially by some of the younger physicians who often lack confidence in the writing of prescriptions for official medicines where dosage, solubility, incompatibilities and vehicles are involved.

C-Exhibits for Medical Groups. It is also planned that an exhibit will be placed in the building of the Philadelphia County Medical Society presenting the preparations and prescriptions recommended in each of the A. M. A. Journal articles and these exhibits will be photographed and described for general publication and distribution to pharmacists and

hospitals.

It is hoped that pharmacists in many localities will duplicate these exhibits before medical

groups.

Pan-American Cooperation. It is gratifying to announce that the Pan-American Sanitary Bureau, through its director, Dr. Hugh S. Cumming, Surgeon General of the United States Public Health Service and its Assistant Director, Dr. Boliver J. Lloyd, and their staff, have undertaken the translation of the U. S. P. XI into Spanish as an official activity of the Bureau. It is hoped that the Spanish Edition will be available by April next when a large Pan-American Medical Congress will be held in this country.

It is also expected that the medical articles on the use of official medicines, appearing in the A. M. A. Journal will be translated into Spanish and reprinted in the official Bulletin of the Bureau for circulation through the twenty-one republics affiliated in the Pan-American program.

It should be understood, however, that the policy of the U. S. P. Board of Trustees in translating the U. S. P. into Spanish now for four decades has been primarily that it might be available to pharmacists and physicians in Porto Rico, the Philippines, and in Cuba. In the latter Republic, the U. S. P. has been adopted as the official Pharmacopoeia for more than thirty years and has been made possible through these years by the cooperation of the pharmacists of Cuba and the help of the scientific staff of the University of Havana and especially Dr. Jose Guillermo Diaz.

In the present revision Auxiliary Commissions from Cuba, Porto Rico, and the Philippines have been participating in the revision (see the U. S. P. XI, page viii).

It is expected that each of the other Republics affiliated with the Pan-American Union will eventually issue their own Pharmacopoeia as is now done by Mexico, Brazil, the Argentine and others, but in offering the U.S. P. in Spanish it has been hoped that increased uniformity in nomenclature, tests and standards will be secured on this continent.

Thanks and Recognition for Those who have Made the U.S. P. Eleventh Revision.

The U.S. P. Committee of Revision and Board of Trustees are deeply conscious and gratefully appreciative of the unprecedented loyalty, self-sacrificing labor and large financial help contributed by individuals and organizations during the revision of the Pharmacopoeia.

This help has come not only from American physicians and pharmacists but from many in foreign countries. The close co-operation of the British Pharmacopoeial Commission has been especially gratifying

and points the way to far greater internaparticipation in Pharmacopoeial affairs. It is hoped that within the decade this may be realized by the establishment at Geneva, under the auspices of the Health Organizations of the League of Nations, a Secretaryship of Pharmacopoeias. This is now under serious consideration.

A compilation is now being made of the contributions to the revision of the U. S. P. XI that suitable recognition may be given to those who have taken part in the program. It is only those who have demonstrated a willingness to contribute of their knowledge and time to the scientific or administrative work of the Pharmacopoeia who have earned the right to actively participate in Pharmacopoeial affairs; particularly must the Pharmacopoeia be lifted from the level of politics.

Society Activities

Executive Committee Proceedings

At its meeting on February 13, 1936, the Executive Committee accepted the following report, adopted its recommendations and directed publication in the Journal.

REPORT OF THE COMMITTEE TO INVESTI-GATE THE APPOINTMENT OF A LAYMAN AS DIRECTOR OF THE DEPARTMENT OF HEALTH AND PHYSICAL EDUCATION IN THE STATE DEPARTMENT OF EDUCATION

The Committee appointed by President Sondern, January 6, 1936, to investigate the appointment of a layman as director of the Department of Health and Physical Education in the State Department of Education feels that it is necessary to draw attention to certain facts as they present in chronological order.

Some time previous to April 13, 1935, the State Department of Education decided to combine the two divisions of school medical inspection and physical education. The medical inspection work had for many years been under the direction of William A. Howe, M.D., and Physical Education was under the temporary direction of Hiram A. Jones Ph.D. Dr. Dean Smiley had, after the retirement of Dr. Howe, been serving as provisional appointee, this appointment having been made by the State Education Department.

Õn April 13, 1935, appears:

BULLETIN OF THE STATE OF NEW YORK DEPARTMENT OF CIVIL SERVICE STATE, COUNTY, AND VILLAGE EXAMINATIONS Published June 1, 1935, Page 6. Under special conditions: State Unwritten Examinations later than June 1, 1935, For the

following positions no written examination or appearance of candidates will be required June 1st, but candidates will be rated on training, experience and general qualifications. Ratings may be affected by information furnished in the applications and it is essential that candidates show in detail in their applications all experience that may be of value.

Paragraph 80: "Director of Health and Physical Education, Department of Education. One appointment expected at \$6250. Duties: Under general direction of the Commissioner of Education, to plan and direct the health service, health teaching and physical education programs conducted by the state in the public schools and teaching institutions and to do related work as required. Candidates must be graduates of a college or university registered by the University of the State of New York; should hold the degree of doctor of medicine or doctor of philosophy or equivalent degree with a major in health and physical education; and must have had a combined total of at least five years of successful experience in teaching or in an administrative or supervisory capacity, either in the field of health education or physical education or in both. Additional credit will be given for graduate or professional study in school administration, and other fields closely related to health education and physical education; for contributions to the literature of health education and physical education; and for other special or unusual achievements in this field.

Several candidates appeared for oral examination before the single examiner appointed by the Civil Service Commission. As a result of the examination, the provisional appointee, Dr. Smiley, was ranked fourth, and as we understand the law, the Commissioner of Education was compelled to select one of the first three. For reasons that are not entirely germane to our report, neither the second nor third candidate was, in the opinion of the Commissioner, fitted for the position. The examination was held June 1st and the results announced October 9th.

This examination was oral, and the ratings were entirely those of the single examiner, Dr. Jesse F. Williams, Head of the Department of Physical Education, Teachers College, Columbia University.

On October 17, 1935, Dr. Walter A. Leonard of Cambridge, N. Y., the President of the New York State Sanitary Officers Association, directed a letter to our President.

From the available facts, it seems that on October 24, 1935, Commissioner Graves of the New York State Education Department appointed Mr. Hiram A. Jones over the protest of the New York State Sanitary Officers Association, and other interested bodies including the New York State School Physicians Association, New York State Health and Physical Education Association, and the State Teachers Association. Later these societies sent a letter outlining their position to every member of the Board of Regents, and further through their delegated authorities, lad conferences with the Board of Regents and the Commissioner of Education.

Dr. Leonard states that he referred the matter to our Committee on Public Relations and to Dr. Mitchell, President of the New York State School Physicians Association. He also refers to his communication with Dr. Graves.

Our Public Relations Committee had a conference October 26th at which time the Chairman, Dr. Warren, invited Commissioner Graves to meet with the members and discuss several important matters concerning health and physical education in schools, the program developed by Dr. Smiley, and the appointment of a director of the combined positions,

With this background, I proceed to explain that Dr. Jesse F. Williams, the examiner designated by the State Civil Service Board, was a former teacher of Mr. Jones, and that he has by one of his recent communications presented evidence not favorable to the medical profession, which is so revealing that we feel quite

certain that no court of appeal would hold that he had been a fair examiner. I quote a few of his sentences taken from "Educational Function of Specialists" published in Teachers College Record, December 1935. "... to expect the physician to be an expert in the development of health is to continue the practice of regarding the physician as also priest and prophet," "the physician is generally the most narrowly specialistic, the most exclusive lone wolf in the whole educational pack," "the practice of medical groups of viewing health and physical education in the terms of disease prevention is the real reflection upon the medical services in education." "Medical persons generally fail to understand what development really means, and what vitality and organic vigor represent." "This present activity of medical groups is an excellent example of medical narrowness, of medical intolerance, and of medical failure to appreciate the problems of educating children for life." Such was the background of the examiner.

The examination was regularly advertised and regularly held, but I feel that two essentials were neglected in the preparation for the examination:

1. That the position should be held by one having the degree of Doctor of Medicine.

2. That an interested examiner should not have been requested to conduct the examination.

In view of these facts, I feel that certain definite action should be taken by the Medical Society of the State of New York.

- That the qualifications for this and other such positions closely associated with the dedivery of medical service should be reviewed by our Society and appropriate suggestions made before the examinations are advertised.
- That in view of the facts above stated we ask the Civil Service Reform Association to investigate this recent examination and appointment and render a report of their findings.
- 3. That we acknowledge our indebtedness to our President, Dr. Sondern, and to Dr. Leonard for their excellent work and for their valued protests, all made in the interest of the people and the medical profession, and that we also express our thanks to Dr. Harold H. Mitchell, President of the New York State School Physicians Association, Dr. Ellis H. Champlin, President of the New York State Health and Physical Education Association, to our Public Relations Committee, through Chairman Warren, to Dr. Joseph S. Lawrence, our Executive Officer, and to the legion of others who endorsed the appointment of a graduate in medicine as the head of such an important State Department.
- 4. We believe that in fairness to all concerned such Examination Boards should consist of three members.

ARTHUR J. BEDELL

Committee on Economics

P.IV.A.—Public Works Administration. Federal money, loaned to local civil authorities, supports award of contracts for local improvements. The contractor is engaged in private enterprise and his workmen are in the same status as those of any other employer in New York State. Injured employees come under the New York State Compensation Law. Physicians who have enrolled thru the County Medical Society may render medical care. The injured workman has free choice. Bills for service of physician should be rendered to the employer, or "carrier" if known.

W.P.A.—Works Progress Administration. Federal employment as a relief measure on subsistent wage. When an employee suffers injury arising out of employment he is a beneficiary of the United States Employees' Compensation Law. Regulations provide that District administration officers shall make contact with local medical societies and arrange for care of injured workmen. They further provide that "available" governmental facilities shall be used when By authority of the Executive Committee of the Medical Society of the State of New York, the Committee on Economics has proposed that the same conditions as specified in the State Workmen's Compensation Law be applied. has been arranged that each County Medical Society, thru its Workmen's Compensation Board, may file in the District W.P.A. offices, the same list of physicians which it has certified to the Industrial Commissioner. For the five counties of New York City the headquarters is 45 West 18 Street, New York City, Mr. T. H. Anderson, Compensation Officer, and Mr. J. M. Hamblin, Assistant Compensation Officer. For the other counties of the State, headquarters is at Albany, New York, Mr. C. M. Whipple, Director, Old Post Office Building.

Authorization for care should be obtained, when possible by telephone. Reports must be made promptly, and bills for service should conform to Workmen's Compensation fee schedule, and should be rendered

to the District Headquarters or as otherwise directed from the nearest local sub-office.

Important. The dependants of W.P.A. workmen are NOT entitled to benefits under this arrangement and the workmen themselves are not entitled to care for conditions which do not arise out of a causal relationship incident to the employment. In all such instances the question of compensation for medical care must be taken up with the "welfare" or "relief" officers of the com-The physician is apt to be mistreated because both parties may deny responsibility for the medical care. only remedy seems to be in energetic action by local County Medical Societies in the creation of an informed public opinion and the focusing of that criticism upon responsible welfare agencies.

T.E.R.A.—Temporary Emergency Relief Administration—(New York State Wick's Law), and in New York City. E.R.B.—Emergency Relief Bureau, is the local equivalent to T.E.R.A. in other counties. "Medical Relief" comes under this heading with State headquarters of T.E.R.A. at Albany, and E.R.B. headquarters in New York City, Dr. C. F. McCarty, Director, 20 East 21 Street, New York City.

Physicians must have authorizations, and work under very detailed rules and regulations laid down by T.E.R.A. and E.R.B. Bills are to be rendered at special schedule, and filed with local authority headquarters.

The Wardwell Commission has recommended that T.E.R.A. and E.R.B. be transferred to the Department of Social Welfare. The matter is pending before the State Legislature and some rumors have it that the emergency relief agencies will shortly pass out of the picture.

Confusion may be further occasioned from the fact that on some P.W.A. jobs the contractor may have W.P.A. workmen as supervisors, etc. The physician who wants to be compensated for his services must carefully identify the status of his patient and govern himself accordingly.

Committee on Legislation

Bulletin Number 5

February 7, 1936

As previously announced, the annual conference of county chairman was held in the Hotel Ten Eyck, Albany, on Thursday, February 6th. Minutes of the meeting are being prepared and will be issued later. A list of those present and the action taken on bills, you will find recorded below:

County Societies Represented (28)

Albany	Dr. James F. Rooney
Allegany	Dr. N. H. Fuller

Since our last bulletin the following bills have been introduced. Some of these were available for consideration by the conference and in those instances its action is recorded.

Senate Int 586—Baldwin, authorizes New York City to finance and maintain public clinic or hospital within area bounded by 8th and Lexington Avenues, and 100th and 125th Street Referred to the Cities Committee

Senate Int 644—Egbert, adds new section 168 Libor Liw, providing no person employed in a Stite hospital shall be allowed to work more than eight hours a day and eight consecutive hours shall constitute a day's work and not more than 40 hours a week's work Referred to the Labor Committee Tabled by conference

Senate Int 655—Buckley, Assembly Int

Sente Int 655—Buckley, Assembly Int 794—Reoux, for organization and government of counties, providing alternative forms except for counties in New York City, and for submitting one or more forms of government to electors, various forms being county president, counti manager, council-president, council manager and selective Referred to the Internal Affairs Committees No action by conference

Sente Int 666—Doyle, Assembly Int 835—Williams, provides for payment of compensation medical and hospital expenses of firemen by cities other than New York, towns and villages having a paid fire force, who are injured in or taken sick as a result of performance of duty. Referred to the Cities Committee in the Senate and General Laws Committee in the Assembly Approved by conference

Sente Int 685—McNaboe, adds new section to the Public Welfare Law, providing no veteran or member of veteran's family shall be denied relief by reason of acceptance of payment of adjustment service certificates Referred to the Finance Committee No action by conference.

Senate Int. 727—Howard, amends the Labor Law by providing 48 hours shall constitute a legal week's work, eight hours a legal day's work, and requiring one day rest in seven for all State employees employed by a State department, board, agency or council or by any institute including those engaged in care and guarding of person and property or performing nursing, kitchen or other service and those caring for public buildings and grounds. Referred to the Labor Committee. Tabled by conference.

Senate Int. 731—Wicks; Assembly Int. 836—Wadsworth; amends Chapter 798, Laws of 1931, by extending to April 1, 1936 life of Temporary Emergency Relief Administration. Referred to the Finance Committee in the Senate and the Relief and Welfare Committee in the Assembly. No action by conference.

Senate Int. 755—Coughlin, amends the Civil Service Law by prohibiting removal of veteran nurses except for incompetency or misconduct shown after hearing; also giving preference in case of abolished positions to veterans and exempt volunteer firemen, and relative to certification for their transfer. Referred to the Civil Service Com-

Senate Int. 764—Esquirol; Assembly Int. 919—E. S. Moran; amends the Insurance and Membership Corporations Laws, for formation of non-profit service indemnifying corporations whereby policy, holders shall be indemnified for amounts paid out for medical and surgical care and treatment and nursing and hospital care, directors to be selected from list of persons nominated by president of county medical society. Referred to the Insurance Commit-

Senate Int. 765—Esquirol; Assembly Int. 920—E. S. Moran, adds new section to the General Business Law, permitting a hospital supported in whole or part by public funds or by private subscriptions or which receives exemption from taxation under section 4, Tax Law, to employ physicians and surgeons under contract or salary arrangement for medical diagnosis and treatment of patients only when such patient is a public charge; in all other cases to be rendered to patients independently of other hospital charges and under contract between patient and physician. Referred to the Judiciary Committee in the Senate and the Codes Committee in the Assembly.

Senate Int. 800—Esquirol; Assembly Int. 889—McCreery;\ amends the Decedent Estate Law by providing damages recovered in action for negligence or wrongful act or default causing death of decedent, must

be exclusively for benefit of husband or wife and dependent children, instead of next of kin, and if none, then of decedent's parents, and if none, then of statutory disand making other changes. tributees, Referred to the Judiciary Committees.

Assembly Int. 796—Ehrlich, amends the Public Welfare Law by providing person in need of medical care other than hospital treatment shall be attended by his family physician or one of his own choice practicing in vicinity, who shall be employed by public welfare official, otherwise such official shall select the physician. Referred to the Relief and Welfare Committee. Approved by conference.

Assembly Int. 802-Lo Re, adds new section to the Public Welfare Law providing no war veteran otherwise dependent on public funds shall by reason of receiving payments on adjusted service certificates be deprived of home or work relief. Referred to the Relief and Welfare Com-

mittee. No action by conference.

Assembly Int. 814—Swartz, amends the Correction Law by providing a prisoner sent to a hospital because of sickness must be kept in custody of officials in charge of jail to which he is committed, instead of custody of chief officer of hospital. Referred the Penal Institutions Committee. Approved by conference.

Assembly Int. 833—Ostertag, amends the Labor Law by making 48 hours a legal week's work for all classes of State employees whether employed by a department, board, commission, agency, bureau or council or by an institution, including those caring for persons and property or performing nursing and other service, eight consecutive hours in any 24 shall constitute a legal day's work. Referred to the Civil Service Committee. Tabled by conference.

Assembly Int. 864—Hill, amends the Education Law by providing practice of medicine shall not be construed to prevent practice of chiropractic and authorizing Regents to issue licenses. Referred to the Education Committee. Opposed by conference.

Assembly Int. 865—Hill, adds new Art. 48-a, Education Law, for the practice of chiropractic; for a state board of examiners, and for the issuance of licenses. Referred to the Education Committee.

Opposed by conference.

Assembly Int. 893—Rossi, amends the Conservation Law by providing that applicant for a license must show that within a year immediately preceding he has submitted to test for color blindness and successfully passed it. Referred to the Conservation Committee.

Assembly Int. 963-Parsons, adds new

section to the Lien Law, giving public hospitals and private hospitals supported in whole or part by charity, a lien on rights of action, claims or demands of any person receiving treatment and maintenance on account of personal injuries received within one week prior to admission and as a result of negligence. Referred to the General Laws Committee.

Comment: This bill is identical with the one carried by Assemblyman Potter last year, and provides for hospitals alone.

Action on bills: Senate Int. 377, Quinnbringing poor person into State—3rd reading. Assembly Int. 30, E. F. Moran—jury duty—3rd reading.

Hearings: Feb. 11—Sen. Int. 563, Byrne—and Sen. Int. 12, Buckley—jury duty—hearing before Senate Judiciary Committee

Special Bulletin

February 14, 1936

Senate bill Int. 764—Esquirol; Assembly Int. 919—E. S. Moran (see digest of bill given below); to amend Sections 452 to 461, Insurance Law, 11, Membership Corporations Law, for formation of non-profit service indemnifying corporations whereby policy holders shall be indemnified for amounts paid out for medical and surgical care and treatment and nursing and hospital care, directors to be selected from list of persons nominated by president of county medical society, was reported out of committee in the Assembly on Thursday, February 13.

About the same time the Executive Committee, in session in New York, expressed its opposition to the bill on the ground that it is very definitely a voluntary health insurance scheme.

Some confusion may arise because there is an impression that the bill was introduced at the request of the State Society. The Executive Committee wishes to have this error corrected.

We are informed that the amendment is intended to permit of the duplication at Rhinebeck, Dutchess County, of the Brattleboro, Vermont plan of providing medical care to people of its community.

Will you communicate with your legislators immediately and inform them correctly regarding the bill. We must act promptly and unitedly if we hope to have this measure defeated.

Digest of Moran bill

Int. No. 919—In Assembly. An Act to amend the insurance law and the membership corporations law, in relation to non-profit service indemnifying corporations. Section 1. Article fourteen of chapter thirtythree of the laws of nineteen hundred nine, entitled "An act in relation to insurance corporations, constituting chapter twenty-eight of the consolidated law," as added by chapter five hundred ninety-five of the laws of nineteen hundred thirty-four, is hereby amended to read as follows:

Article 14

Non-Profit Hospital Service Plans

Section 452. Definition and scope of article. corporation heretofore or hereafter organized under the membership corporations law(s) of the state of * * * who become subscribers to said plan under a contract which entitled each subscriber to certain hospital care (new matter begins here); or any corporation heretofore or hereafter organized under the membership corporations law of the state of New York to be known as a non-profit service indemnifying corporation for the purpose of establishing, maintaining and operating a nonprofit service plan whereby policy holders shall be indemnified for amounts paid out or agreed to be paid out by them for medical and surgical care and treatment, nursing care and hospital care, under the terms and conditions of policies issued to them after the conditions and terms and premium rates of such policies have been approved by the superintendent of insurance, (new matter ends here) shall be governed * * * * * * same as old law. () old matter to be left out.

Section 433. Incorporation. 1. Persons desiring to form a non-profit hospital service corporation or a non-profit service indemnifying corporation shall incorporate * * * 2. At least a majority of the directors of such corporations, except a non-profit service indemnifying corporation, must at all times directors or trustees * * * (New matter begins here) 2-a. The directors of a non-profit service indemnifying corporation, chosen at the first annual and each subsequent meeting at which directors are chosen, shall be selected from a list of persons nominated by the president of the county medical society in which such indemnifying corporation is domiciled. (New matter ends here). 3. Every certificate of incorporation of a non-profit hospital service corporation and non-profit service indemnifying corporation is domiciled.

Section 454. Contracts. I. Any corporation subject to the provisions of this article may enter into contracts * * * 2. The rates charged by such corporation * * * 3. Al rates of payments to hospitals made * * * * 4. The provisions of this section shall not apply the a way the first register indeputibing corporation.

to a non-profit service indemnifying corporation.

Section 455. Annual reports of corporations.

Every such corporation shall annually * * *

Section 456. Examinations. The superintendent of insurance, * * *

Section 457. Acquisition costs. All acquisition

* * to such hospital service plans and
service indemnifying plans shall at all times be
subject to the approval of the superintendent
of insurance.

Section 458. Funds. The funds of any

THE TENTH ANNIVERSARY dinner dance of the American-Hungarian Medical Association was held at the Hotel Plaza on the evening of February 1. There was a large attendance, and the net proceeds were turned over to the welfare fund of the society for the aid of needy physicians and their families. The society is largely composed of men who were driven by the distress and unrest in Hungary after the war to seek new homes here. Some 150 to 175 settled in or near New York and others located elsewhere under the Stars and Stripes. Many could not speak English and had to take all kinds of jobs, some as laborers. More prosperous Hungarians already here aided the new arrivals and all are facing the future with hope and courage. The annual dinner dance is an occasion of reunion and good cheer.

Niagara County

THE PHYSICIANS employed by the city of Niagara Falls are opposing the proposal of the Niagara County Medical Society that welfare patients select their own doctors. Dr. Frederick Leighton, spokesman for the city physicians, told the city council the plan would cost twice that of the present system. Dr. R. H. Sherwood, President of the Eighth District Branch of the State Medical Society, and other physicians, argued that the matter ought to be decided on the basis of service given and not merely on economy.

Dr. LYMAN H. WHEELER has been appointed city physician and health officer of Lockport.

Dr. A. Wilmot Jacobson of Buffalo spoke on "Endocrine Disturbances in Children," at the meeting of the Niagara County Medical Society at the Cataract House, Niagara Falls on Feb. 11.

Onondaga County

Addresses were given at the meeting of the Onondaga County Medical Society on Feb. 4 by Dr. Lester R. Mellor, Dr. Harry J. Brayton and Dr. Edgar M. Neptune.

Queens County

NEARLY 150 DOCTORS attended the annual dinner of the Long Island City Medical Society at the St. Moritz Hotel, Manhattan, on Jan. 30. The dinner marked the seventieth year of the organization.

Dr. WILLIAM BIERMAN, director of physical therapy at Beth Israel and Mt. Sinai Hospitals, discussed fever therapy

induced by physical means and recent advances and therapeutic indications on Feb. 7 before the Queens Medical Society at Forest Hills.

Rensselaer County

Dr. John F. Connor was elected president of the medical and surgical staff of the Leonard Hospital at Troy at the annual dinner and meeting of the staff on Feb. 8.

Dr. C. W. Hamm was chosen vice president and Dr. Joseph P. Lasko, secretary-treasurer.

Steuben County

Dr. Leon M. Kysor was re-elected for the tenth time to be president of the Board of Managers of the Steuben County Laboratories at its annual meeting in Bath.

atories at its annual meeting in Bath.
Dr. W. W. Bachman of Bath was reelected vice-president, Dr. H. B. Smith of
Corning re-elected secretary.

Suffolk County

THE MEETING OF THE Suffolk County Medical Society at the Old Oaks Hotel in Patchogue on Jan. 29 was devoted to a discussion of the state pneumonia campaign. Dr. Jesse G. M. Bullowa was the chief speaker.

Warren County

DR. CONRAD R. HOFFMAN, of Glens Falls, who died on Feb. 9 at the age of fifty-five, was president of the Glens Falls Academy of Medicine, Fellow of the American College of Surgeons, Fellow of the A.M.A., and former President of the Warren County Medical Society.

Westchester County

DR. CLARENCE O. CHENEY, Professor of Psychiatry in the College of Physicians and Surgeons of Columbia University and Director of the New York State Psychiatric Institute and Hospital at 722 West 168th street, has been appointed Medical Director of Bloomingdale Hospital at White Plains. Dr. Cheney was president of the New York Society for Clinical Psychiatry in 1934 and 1935, and is now president of the American Psychiatric Association. He has been chairman of its board of medical examiners since 1933. He is Associate Editor of the American Journal of Psychiatry and of the Psychiatric Quarterly. He is editor of the book "Outlines of Psychiatric Examinations."

LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

Healer Found Guilty of Illegal Practice of Medicine

In a recent prosecution based upon charges of the unlawful practice of medicine by an unlicensed person, the Court of Special Sessions of New York City in finding the defendant guilty handed down an interesting decision.*

The defendant in the case was charged under Sections 1250, 1251, and 1263 of the Education Law of the State of New York with practicing medicine without a license and specifically with having treated one Gertude D— who had investigated the case.

Upon the trial the said investigator testified that she had gone to the office of the defendant on two occasions and that on the first visit she had told him that she was suffering from pain under the arch of the foot and in the calves of her legs. According to her testimony the defendant had undertaken to treat her for her complaints by removing her shoe and pressing her foot with his thumb under the arch until she had told him to stop by reason of the pain that he caused her. He had also rubbed the calves of her legs for some time. She further testified that on the second visit she complained to the defendant as before and also told him that she was suffering from headaches and nervous disorders, and again he undertook to treat her. He again proceeded to exercise pressure under the arches of her feet and he also told her that he would give her a treatment for headache and for nerves. In doing so he stood behind the chair in which she was seated and pressed his hands on her head for about five minutes and also pressed his hand around her neck and rubbed her back from the neck down to the waist, at the same time giving her instructions as to the position she should assume and directing her as to proper breathing. The investigator testified that she had been given a card by the defendant which read as follows:

Fallen Arches Curel
Without Surgery or Medical Apphrations
Walk with ease without arch supports
or Special Shoes
Results Guaranteed
J. H. Hotel II—West Street
New York City
Findicott Room

That card was introduced in evidence, and also another card which bore the defendant's

name, address, telephone, and office hours, and underneath his name bore the word "Healer" and in the lower left hand corner "By Appointment."

The prosecution also offered in evidence as one of its exhibits a receipt likewise bearing the name of defendant, his telephone number, room number, address, the date—December 15, 1934—and the words "to Mrs.—25.00 full treatment Money refunded

if not satisfied Paid c/o 3.00."

On the trial the defendant testified that his treatment which formed the basis of the charges against him had been by prayer, by the placing of the tips of his fingers over the outer garments of the subject over the parts of the body affected by pain. He claimed that he had exerted very slight pressure, if any, in administering this form of treatment. He also claimed that at the time he had treated the investigator he had had before him a picture of Christ and that he had specifically informed her that he was not curing her but that the cure was by the power of God exerted through the defendant. He denied that he had employed rubbing or massage but admitted that he had placed the tips of his fingers upon the garments of the investigator. His defense also included testimony that he was the president and pastor of a church which had been formed about three years previous under the name of The Church of God and that that name had been changed to The First Church of the Divine Revelation and subsequently to The Christian Church of the Divine Revelation. church apparently consisted of twelve members including himself and his wife, offered in evidence upon the trial the minutes of certain meetings of the church which appeared in a book written in his own handwriting. He also admitted upon examination to have received fees from the investigator and from others.

The defendant made a motion upon the evidence for an acquittal relying primarily on the argument that the practices that he had engaged in were exempted from the provisions of the Medical Practice Act by the clause in Section 1262 of the Education Law which reads as follows:

"This period of all trued to prevent or tenets of any church,"

^{*} People v. H----, 157 Misc. 592.

He cited as authority for his position an earlier case—People v. Cole, 219 N. Y. 98, in which it was held that offering prayer for the healing of disease in accordance with the recognized tenets of the Christian Science Church did not constitute the illegal practice of medicine.

The Court, however, concluded that under the circumstances as shown by the testimony upon the evidence upon the trial the defendant was not entitled to the exemption contained in Section 1262 of the Education Law permitting the practice of religious tenets of a church, since the defendant's church appeared to be merely a cloak or screen for the practice of medicine by him in violation of the law. The court, therefore, denied his motion for an acquittal and found him guilty as charged. In the court's opinion it stated in part as follows:

The court is of the opinion that defendant's card which he gave to the investigator, which bears the name of the defendant, the address, telephone and room number, with the words "Fallen arches cured; Without surgery * * * or special shoes; Results guaranteed," together with the treatments testified to by defendant, constitutes a holding out as being able and an offer or undertaking to diagnose, treat, etc., in violation of Section 1250 of the Education Law.

This brings us to the question, although not necessary to this decision, as to whether defendant comes within the exception contained in Section 1262, "the practice of the religious tenets of any church." It may be pointed out that in the present case as well as in the case of People v. Cole (supra) the treatment was for a consideration.

As to the character and extent of the treatments, the testimony of the investigator finds corroboration in the admission of defendant that he applied pressure, even though slight, to the arch of the foot and placed the tips of his fingers against the outer garments of the body. The admissions of defendant, including People's Exhibit 3, above referred to, justify the acceptance of the People's version as to the character and extent of the treatments. If we are correct in this, defendant cannot be exempted by the claim that he was engaged in the practice of the religious tenets of a church. Moreover, as to the church in question, the evidence supports the view that it is but a cloak or screen for the practice of medicine by defendant in violation of the statute. This view is borne out by an examination of the church minutes, its almost negligible membership, defendant's experience and background, and the manner in which he mingled the operations of the church and his office practice. Upon a consideration of all the evidence we are unable to escape the conclusion that defendant's practices are in violation of the

Complaint Concerning Prescription for Dermatitis

A middle aged man consulted a physician

with respect to complaints of rash on his legs, which was found to be a mild form of dermatitis. The doctor wrote out a prescription calling for ammoniated mercury ointment. He referred the patient to another doctor for the purpose of having a Wassermann examination taken.

The patient left the first doctor's office but did not take with him the prescription blank. A short time later the first doctor noticed that the prescription had been left behind and called up the second doctor on the telephone and told him of the prescription which he had previously written. The second doctor decided to give the patient a prescription of bichloride of mercury instead of ammoniated mercury ointment, and after examining the patient he gave him such a prescription.

Thereafter the Wassermann proved to be negative. Neither of the doctors ever

attended the patient again.

Subsequently an action was brought against both of the doctors and against a drugstore and its pharmacist, charging all of them with having been negligent in connection with the issuance and filing of the prescription, the claim being that the plaintiff's rash was increased rather than cured by the substance that was prescribed.

The case came on for trial in the Supreme Court as a jury trial and at the close of all the testimony the complaint was dismissed upon motion as to the first doctor. The issues in the case were submitted to the jury as to the remaining defendants and the jury determined that there was no cause of action against any of them.

Claimed Negligence Upon Death of Fetus

A physician who specialized in obstetrics attended a woman about forty years of age during her delivery. She gave birth to a normal child and had an uneventful recovery.

She returned to the doctor some time later and told him that she thought she was pregnant and complained that she had been bleeding. He examined her and found that she was about four months pregnant and gave her advice as to rest in bed and told her to return about two weeks later for further examination, but she did not return for over two months. He found that the pregnancy had not progressed normally and that her uterus was smaller. He kept her under observation for a month and he found then that her uterus was still smaller. He decided that most of the products of conception had been absorbed and that the re-

mainder of the same would probably absorb

necessary at that time

The doctor advised the patient of these conclusions and told her to keep in touch with him from time to time. She failed to do so and the doctor never heard from her again until some time later when he was served with a summons and complaint starting a malpractice action against him

The complaint charged that the defendant failed to discover a dead embryo in the uterus of the plaintiff and that he failed to take any steps to relieve the condition

The case came on for trial and when the plantiff's attorney found that the doctor was ready to defend the case he voluntarily discontinued the action, thereby admitting that he was unable to prove any cause of action against the doctor

Across the Desk

"Look at the D- Thing Now!"

impossible

THE CHARCI IS now made that after its long rough and tumble fight for life, the Copeland bill lits been "so bridly clawed by Senitors, chevied by advertising and publicity mediums and local interests" that it is "in many respects even weaker than existing legislation." This attack on the bill appears in The Consumer, published by the Consumers Division of the Department of Labor at Washington. It is now "as nearly futile and innocuous as the most resourceful drug manufacturer, advertiser, and salesman could desire" declares the American Journal of Public Health, and it should be "altered

or voted down" And the bill is also raked at the sume time by a hot broadside in the AMA Journal from the AMA Bureau of Legal Medicine and Legislation, which declares some of its provisions so bad that "they open the door wide for fraud and danger"

For example, the measure proposes to penalize misbranded drugs and devices and to ban false or misleading advertising. But who is to say whether the label and the advertisement is false or true? According to the bill it is to be decided by an appeal to "demonstrable scientific facts or sub stantial and reliable medical or scientific opinion" That sounds good, but when we come to look into it a bit, we discover that "medical opinion" is defined to mean the opinion of "the legalized professions of the healing art"-a phrase so vague that some say it would include 'the opinions not only of doctors of medicine and of dentists, pharmacists and registered nurses, but the opinions also of chiropractors, osteopaths, naturopaths, optometrists, chiropodists, and midwives, and in some states of other price titioners, according as one or another class is licensed by the laws of the state" In credible? Not at all. That is the sober view of the AMA Bureau of Legal Medicine
It is easy to imagine millionaire makers
of fake nostrums parading plenty of silk
Initial professors of 'the healing art' before
ignorant juries and "getting away with
murder" under this wide open clause Successful prosecution would become almost

As Water-tight as a Colander

As if that were not enough, this kindly measure provides that the Secretary of Agriculture is not required to prosecute "mmor violations of this act" whenever he deems 'written notice or warning" sufficient As this decision will be in the hands of subordinate officers receiving small salaries, the danger needs no explanation too in case of prosecution, interminable delays may ensue, for the offender must first receive a notice and have a hearing, receive notice of the decision and have a second hearing if necessary, and then be prosecuted A dealer, furthermore, who handles misbranded articles and advertises them "in good faith" and in ignorance of illegality cannot be punished if he gives the name and address of the person from whom he bought them The amount of "good frith" and ignorance that will be brought into court by retail dealers in nostrums will undoubtedly be colossal Just how the government is going to convict anybody under this highly porous measure is a prize puzzle. It seems about as watertight as a colander

The blatant advertising of quack remedies for dangerous diseases was supposed to be hard lit by the original Copeland bill, but by some drastic dentistry its teeth have nearly all been pulled. It formerly contained a list of forty two aliments in which advertising was prohibited or restricted. There

are thirty-four in the similar Canadian drug act. Yet the present Copeland bill forbids advertising claims only in regard to Bright's disease, cancer, tuberculosis, infantile paralysis, venereal diseases, and heart and vascular diseases. It would certainly be interesting to know just how and why the list was whittled down from forty-two to six. A lot-of strong language has come from Washington against the "chislers." What about the whittlers?

Plenty more could be said, but this is more than enough to show up the character of the measure that may soon be rushed through onto our statute books. passed the Senate and may be reported to the House at any time. To pass this inadequate and futile bill will expose the country to grave dangers, as pointed out by the A.M.A. Legal Bureau: It will not protect the consumer, it will throw obstacles in the way of effective prosecution, it will exclude any effective law from the statute books for years to come, and it is likely to be taken as a pattern for state laws. All in all, would it not be better to kill this emasculated, deformed, legislative infant in its cradle-a "mercy-killing"-and hope for a healthier specimen next time?

Few are Starving, But —

While it is true that few people are dying of hunger in our industrial slump, investigation shows that family rations have been widely cut down to a point where vitality is sapped and resistance to disease sinks below the danger line. The health of low-income families, and especially of the little children, may be permanently impaired. The U. S. Public Health Service has just published the findings of an inquiry into the diets of low-income groups in New York City, five northern and one southern industrial cities, a southern cotton-mill area, and a soft-coal region.

What will interest us more especially are the conditions exposed in New York City and in the northern industrial towns (one of them Syracuse) which no doubt typify the manufacturing cities dotting this state. Miss Dorothy G. Wiehl, who writes the report, believes in fact that the data "are fairly typical of low-income families of the large industrial cities in the north," though local observation and experience may convince observers that some of our towns are better off, and some perhaps worse. The data

were gathered in 1933, and allowance should be made for any rise or fall since.

Teetering on the Brink of Danger

To weigh the danger of diets that are too scanty, the investigators have adopted the estimate of the Bureau of Home Economics of the Department of Agriculture, that 3,000 calories a day is an "adequate" energy supply per adult male and 2,700 calories is a "reasonable minimum." Women and children are rated to correspond, and the entire family is then evaluated accordingly. Families getting less than the "adequate" supply of calories are obviously teetering on the brink of danger, and families getting less than the "reasonable minimum" are definitely in peril.

"How much meat and fish did your family eat last week?" was one of the questions put by the investigators. "How much potatoes, eggs, bread, cereals, fats, sugar, syrup, jelly, fresh and canned vegetables and fruits, dried legumes, dried fruits, milk?" "What is the weekly income of the family?" "With all the inquiries that are probing into our family life, the proverbial goldfish will soon be a paragon of privacy in comparison.

But the patient poor answered all these questions, and gave the data necessary to tell us how they are faring. Not very well, according to the tables of figures and the lines that twist and turn this way and that on the charts for "potatoes," "eggs," etc. The families are sorted out, like big and little apples, into those on home relief, on work-relief wage, on weekly pay of less than \$2 per member of the family, less than \$3, less than \$4, less than \$5, all the way up to \$6 or more.

In New York City half the families on home relief were found living on a diet below the danger line, and three-quarters of those on work-relief wage were in the same plight. So were seventy per cent of the families earning less than \$3 per week per member, and sixty per cent of those carning less than \$4 per member. And more than half the families investigated were found to be below the \$4 class.

Milk is so essential to children that special paragraphs in the report are given to it. Sherman is cited as saying that milk "is the surest means of providing an adequate intake of calcium well-balanced with desirable amounts of phosphorus, of protein, and of the vitamins." It is encouraging to find

that in New York City the average milk consumption in every group, even the poorest, was above the minimum considered desirable, and in the higher groups it was nearly up to the 'adequate' mark

In Smaller Manufacturing Towns

Turning to the five northern industrial cities (Baltimore, Cleveland, Detroit, Pittsburgh and Syracuse) which are supposed to give a line on northern manufacturing towns in general, we are told that more than half of those on rehef and of those examing less than \$3 a week per member of the family were on a diet below the danger line and some of these families reported very acute food shortages." It is in such families that disease harvests easy victims, and the physician finds his efforts sadly hampered by the fact that his patient has little or no resistance or recuperative power.

Other surveys have shown a clear relation between income and illness—the less the one, the greater the other—and who can doubt that impoverished diet plays its part in the sinister ratio? Figures have proved that families with no employed workers have about fifty per cent more cases of disabling illness than those with a full time worker.

Sickness and denth do not writ for actual starvation to do its work. A gradual, insiduous breaking down of the natural defenses is enough, and any one of half a dozen diseases will leap in and seize its victim. That is the situation that exists all over our land today, and the longer the depression lasts the worse it grows the lower vitality ebbs, the weaker resistance becomes. The best medicine for it will be whirring wheels, smoking chimneys, rusting pay envelopes. The doctor who can bring that remedy, be he political, financial or industrial, will be the man of the hour

A Task Worth While

Part of the blame for the slump in milk sales during the depression should be laid to birth control, said Health Commissioner John L. Rice the other day, addressing a meeting of milk producers. This suggests a new slant for the milk advertising campaign Romance, mother-love, the bibble of little voices, can give the ads a fivor they have lacked thus far. The birthrate has sunk from 35 per 1,000 at the turn of the century to 13 per 1,000 Advertising

is mighty Can it boost the rate to its former level? Here is a task worth while

THE PAYMENT OF THE veterans' adjusted compensation will give some of them the ability to settle the doctor's bill—or to buy a second-hand car and take a vacation in Florida. Which will it be? Two guesses are allowed

A Good Figure to Slenderize

PRELIMINARY FIGURES from the Census Bureau state that there were over 96,000 first admissions to the 467 mental hospitals in the United States in 1934. What this tragic figure brings to mind is the probable fact that 96 000 more will be admitted this year, and another 96,000 next year Where are those prospective victims now? Is it possible to locate and save them while their mental troubles are in the incipient stage? Tew things are sadder than a wrecked and disordered mind and while we are busy in our splendid work of preventive medicine for physical ills, let us help the psychopathic experts who are tackling the problem of dementia precox, and the school physicians and educators who are laying plans to dis cover and aid little minds that do not tick quite right Wouldn't it be inspiring to see that dread figure of 96 000 dwindle grace fully downward year by year?

"Doctor, Shall I Study Medicine?"

WHAT SHALL THE DOCTOR reply when some fine young fellow of his acquaintance asks his advice about studying medicine? An Indiana doctor, faced with this question, referred it to Dr Olin West, Secretary of the AMA, and Dr West, in his reply. stated plainly the financial risks of a medical career, but also said that if the young man had all the good qualities he would no doubt succeed Isn't there also another consideration? Some men have it "in their blood' to be physicians. For them there is no other life Just as the artist must print and the singer must sing, so they must heal the sick They would rather be poor in the practice of medicine than rich in anything else Are they not entitled to their chance? The man who thinks of medicine as a 'good business" may well be told to close the door as he goes out, but the one who thinks of it as the sailor thinks of the stars is the man who is going to help make the medicine of the future what we all want it to be

The Physician's Income Tax

General instructions for computing the Federal income tax are printed on every income tax blank, but the provisions which affect doctors are discussed in more detail in the A.M.A. Journal of January 11. We quote and condense the most important paragraphs below. Any additional information desired can be obtained at local internal revenue offices.

Gross and Net Incomes: What They Are

Gross Income.—A physician's gross income is the total amount received during the year for professional services, regardless of when services were rendered, plus money received as profits from investments and speculation and other sources.

Net Income.—Certain professional expenses and the expenses of carrying on any enterprise in which the physician may be engaged for gain may be subtracted as "deductions" from the gross income, to determine the net income. An "exemption" is allowed depending on marital status during the tax year. These matters are fully covered in the tax blanks.

Earned Income.—In computing the normal tax, but not the surtax, there may be subtracted from net income from all sources an amount equal to 10 per cent of the earned net income, except that the amount so subtracted shall in no case exceed 10 per cent of the net income from all sources. Earned income means professional fees, salaries, and wages received as compensation for personal services, as distinguished from receipts from other sources.

The first \$3,000 of a physician's net income from all sources may be regarded under the law as earned net income, whether or not in fact earned within the meaning set forth in the preceding paragraph. Net income in excess of \$3,000 may not be claimed as earned unless it in fact comes within that category. No physician may claim as earned net income any income in excess of \$14,000.

Deductions for Professional Expenses

A physician is entitled to deduct all current expenses necessary in carrying on his practice. The taxpayer should make no claim for the deduction of expenses unless prepared to prove the expenditure by evidence. The following statement shows what such deductible expenses are:

Office Rent.—Office rent is deductible. If a physician rents an office for professional purposes alone, the entire rent may be deducted. If he rents a building or apartment

for use as a residence as well as office, he may deduct a part of the rental proportionate to the space used for professional purposes. To entitle him to deduction he must have an office there, with regular office hours. If a physician owns the building he cannot charge himself with "rent."

Office Maintenance,—Expenditures for office maintenance, as for heating, lighting, telephone service and the services of at-

tendants, are deductible.

Supplies.—Payments for supplies for professional use are deductible. Supplies may be fairly described as articles consumed in the using; for instance, dressings, clinical thermometers, drugs and chemicals. Professional journals may be classified as supplies, and subscription price deducted. Amount expended for books, furniture and professional instruments and equipment. "the useful life of which is short," generally less than one year, may be deducted; but if such articles have a more or less permanent value, their purchase price is a capital expenditure and is not deductible.

Equipment.—Equipment comprises property of a more or less permanent nature. It may ultimately wear out, deteriorate or become obsolete, but it is not in the ordinary sense of the word "consumed in the using."

The cost of equipment, such as is described above, for professional use, cannot be deducted as expense in the year acquired. Examples of this class of property are automobiles, office furniture, medical, surgical and laboratory equipment of more or less permanent nature, and instruments and appliances constituting a part of the physicians professional outfit, to be used over a considerable period of time, generally over one year. Books of more or less permanent nature are regarded as equipment and the purchase price is therefore not deductible.

Although the cost of such equipment is not deductible in the year acquired, it may be recovered through depreciation deductions taken year by year over its useful life, as described below.

No hard and fast rule can be laid down as to what part of the cost of equipment is deductibe each year as depreciation. As fair rates of depreciation, the following have been suggested: automobiles, 25 per cent a year; ordinary medical libraries, x-ray equipment, physicial therapy equipment, electrical sterilizers, surgical instruments and diagnostic apparatus, 10 per cent a year; office furniture, 5 per cent a year.

Medical Dues.—Dues paid to societies of a strictly professional character are deductible. Dues to social organizations, even though limited to physicians, are personal expenses and not deductible

Postgraduate Study —The Commissioner of Internal Revenue holds that the expense of postgraduate study is not deductible

Traveling Expenses — Traveling expenses, including amounts paid for transportation, meals and lodging, incurred in professional visits to patients and in attending medical meetings for a professional purpose, are deductable.

Automobiles —Payment for an automobile is a payment for perminent equipment and is not deductible. The cost of operation and repair, and loss through depreciation are deductible. The cost of operation and repair includes the cost of gasoline, oil, tires, insurance, repairs, garage rentil (when the garage is not owned by the physician), chauffeurs' wages, and the like

If an automobile is used for professional and also for personal purposes—as when used by the physician partly for recreation or so used by his family—only so much of the expense as arises out of the use for professional purposes may be deducted

What has been said with respect to auto mobiles applies with equal force to horses and vehicles and the equipment incident to their use

Miscellaneous

Laboratory Expenses—The deductibility of the expenses of establishing and maintaining laboratories is determined by the

same principles that determine the deductibility of corresponding professional expenses Laboratory rental and the expenses of laboratory equipment and supplies and of laboratory assistants are deductible when under corresponding circumstances they would be deductible if related to a physuran's office

Losses by Fire or Other Causes—Loss of and damage to a physician's equipment by fire, theft or other cause, not compensated by insurance or otherwise recoverable, may be computed as a business expense and is deductible, provided evidence of such loss can be produced. Such loss is deductible, however, only to the extent to which it has not been made good by repair and the cost of repair claimed as a deduction.

Insurance Premiums — Premiums paid for insurance against professional losses are deductible. This includes insurance against drinages for alleged impractice, against liability for injuries by a physician's automobile while in use for professional purposes and against loss from theft of professional equipment and damage to or loss of professional equipment by fire or otherwise. Under professional equipment is to be included any automobile belonging to the physician and used for strictly professional purposes.

Expense in Defending Malpractice Suits—Expenses incurred in the defense of a suit for malpractice are deductible as business expense

REVIEWED

The Popular Practice of Fraud. By T. Swann Harding. Octavo of 376 pages. London: New York, Longmans, Green & Co., 1935. Cloth, \$2.50.

A refreshing change from the old scare head type of muck raking. Mr. Harding holds the mirror up for all of us to take a look, and what a sorry reflection we find, for we are all there, both the just and the unjust. All suckers, and we smile to show that we like it. Even the hard boiled M. D.'s who insist in taking our "stuff" ethically, and how!

We are all frauds, only some of us are more astute than the rest, who, in their turn, are taken in by those still more slick. We take all of our emotions, from fear of death, to fear of ridicule or personal appearance, and we pay the slick boys \$700,000,000 a year to play on these emotions, and we like it! And we clamor for more.

Most of us are not geared for the Twentieth Century, except chronologically, and we fall for the same old stuff, only it is served up to us as a pseudo-science, with a patter of vitamins, restored vigor, how bad our bodies smell, or the things even our best friends hesitate to tell us. The bogey of fear is worked overtime as a selling agent. The cancer and diabetic ghouls are still reaping a fruitful harvest; the more preposterous the claims, the bigger the financial reward. Madame's bosom can be made large or small as desired, by the same cream, applied with reverse "English"!

Why try to save these morons from themselves by the enactment of prohibitory laws? This is the nice question the author evolves after a resume of the high pressure advertising methods which creates a market to sell worthless truck to a people who do not need it, but who lack the mentality to resist the honeyed "sales talk". He develops an ironic humor which is as inimitable as it is naive. He also stresses the need of a real "food standard," statutory, if need be, as a remedy, and this is self evident.

The author extends his sympathetic respects to the harassed Federal agents who attempt to enforce the present inadequate law, and reveals how a richly endowed advertising lobby, with the patent medicine interests, are adroitly thwarting every effort that is being made, to whip them into line, and intersperse at least a morsel of truth, into their bombastic claims. When the millions of plunder lost to these same interests by this type of legislation are considered, their loud cries of "government interference in legitimate business" can be intelligently discounted.

In conclusion, let us agree with the Psalmist, that verily "All is indeed vanity", but that nobody ever dreamed of the millions that were in it, till "legitimate advertising" showed the way. A good book, well written; let us read it well, and profit.

THOMAS F. NEVINS

General Ophthalmology: A Short Treatise for Students and Practitioners. By S. A. Agatston, M.D., 16mo. of 170 pages. New York, John L. Schoenfeld Company, 1935. Cloth, \$2.00.

This newest handbook on ophthalmology has certain features which distinguish it from other well-known works:

a. It is small, and can easily fit into a vest-pocket.

b. It is comprehensive, and reviews the essential features of practical ophthalmology in systematic form.

It should not, however, be confused with the quiz compend designed for undergraduates. It does, however, fill a distinct niche in ophthalmological contributions, for by its summary considerations of the salient features of practical ophthalmology, it serves as a ready-reference guide to the post-graduate medical student and to the busy physician who may be groping for a precise diagnostic term or a concise description or a differential diagnosis.

EMANUEL KRIMSKY

Orthopedics for the Teachers of Crippled Children. By Samuel W. Boorstein, M.D. Duodecimo of 120 pages. New York, Aidem Publishing Company, 1935. Cloth, \$1.50.

As the title of the book explains, it is intended primarily for the use of the teacher of the crippled child. The effect of psychic influence upon these unfortunates can be fully appreciated only by those who have actually seen the results of such influence, both good and bad. This is well brought out by the author, drawn from an obviously very extensive experience. Several opinions expressed in the book, particularly in regard to electrotherapy, are somewhat at variance with those usually accepted, and must be regarded as the result of the author's own observations. The review of disabling conditions found in children is very complete and descriptions are well explained for the guidance of the lay aide. The list of cripples who have attained unusual prominence in world affairs leaves the reader rather envious of those of unsound body. The book on a whole is of considerable merit, and will well repay the brief time required for its perusal.

JEROME WEISS

Aids to Surgery. By Cecil A. Joll, M.D., and Reginald C. B. Ledlie, B.S. Sixth edition. 16mo of 612 pages, illustrated. Baltimore, William Wood & Company, 1935. Cloth, \$2.75.

This volume is the sixth edition of a most remarkable compendium of surgery. Completeness and terseness are its outstanding qualities. It is thoroughly up to date, sparsely illustrated with diagrams, every one of which is to the point. As a quick reference book or as a textbook for pre-exam studies, it has no equal.

GEORGE WEBB

The Spleen and Resistance. By David Perla, M.D., & Jessie Marmorston, M.D. Octavo of 170 pages. Baltimore, Wilkins Company, 1935. Cloth, \$2.00.

A professor of Pathology in one of our medical schools once asked one of his medical students to recite the functions of the spleen. Fearing admission of ignorance, the student replied that he did know it at one time but had forgotten it, whereupon the professor sarcastically exclaimed: A great calamity has befallen the universe. The only man in the world who knew the function of

the spleen has forgotten it!

The spleen has stood jocular comment and has served as a target for medical humor for many years. With recent advances in our knowledge of the Reticulo-Endothelial system, however, it is safe to predict that the spleen will in the near future, occupy the same elevated position as do some of the other viscera concerning which we think we know more. A great step in this direction has been made by the recent publication The Spleen and Resistance by Drs. Perla and Marmorston. These authors are deserving of much complimentary comment for not only did they dare to tread, but also for treading so well on a field "where angels feared to tread."

Only one who is acquainted with splenic difficulties, can appreciate the tremendous task involved in a critical review of all the contradictory and ambiguous literature which has accumulated about the spleen. Such a review has been excellently prepared by the authors of this book, giving a proper evaluation to the various publications on

this subject.

Although the authors deal primarily with the relation of the spleen to infection, the book contains several tangential discussions which are refreshing and illuminating. Thus, in the first two chapters which are brief but precise, a delightful exposition of the authors' knowledge of the comparative anatomy and histology of the spleen is included, followed by a discussion on the significance of the reticular cells in the development of the spleen.

In few, if any, of the available treatises on this subject is there to be found so systematic and scientific a presentation of the changes that occur in the spleen in various infections as is found in this book

381

on the spleen and resistance.

In the subsequent chapters dealing with the role of the spleen in antibody formation, the affect of splenectomy on natural resistance and the relation of the spleen to acquired resistance in latent infection, and compensatory changes following splenectomy, one begins to feel the need for more clinical data which the authors might have provided to make the book more complete. This is especially true of the discussion on compensatory changes following splenectomy.

Experimental workers should find this book especially valuable, since the author deals in more or less complete detail with the experimental phases of the role of the spleen in the above mentioned conditions.

The authors own experimental researches on the relation of copper to resistance and splenic function are discussed, as are also the interpretations of old and recent theories on the roll of the spleen in iron metabolism and its relation to hemoglobin production. The authors' contribution on this phase of splenic function are extremely interesting and should prove to be of practical value.

The summary found at the end of each chapter as well as the final resume are deserving of special comment. Here the authors have shown utmost consideration for the busy man who wishes to get the gist of everything he reads in a summary form.

SILIK H. POLAYES

Mouth Infection: Clinical Histories. By Oliver T. Osborne, Octavo of 119 pages. New Haven [Oliver T. Osborne], 1934. Cloth, \$2.00.

This little book of case histories, which occurred in a prominent physician's general practice, is a very good reminder of the importance of mouth infection in relation to the complete examination and care of the patient.

The author draws a number of interesting conclusions from these cases. Of these a good example is the following, glycosuria can be and perhaps true diabetes mellitus may be caused by mouth infection. With the excellent wealth of material at his disposal, it is to be regretted that more complete histories and careful laboratory data are not included so as to clearly justify the conclusions, which are in the main reliable and true.

The medical and dental professions should be thankful to the author for this added attempt at closer cooperation between medicine and dentistry.

It should be read by every careful physician and dentist. OSCAR RODIN

Les Hallucinations Verbales et la Parole. By Daniel Lagache, M.D. Duodecimo of 184 pages. Paris, Félix Alcan, 1934. Paper, 18 fr.

This is a concise little monograph on the present state of psychiatric thought in France concerning the basis and function of auditory hallucinations. Following a literary discussion of the French psychiatric classical school on this subject, particularly with reference to Seglas and his pupils, the author approaches the problem of hallucinations from the biological and dynamic point of view as contrasted with the mechanical and association tendencies of the last century. This indicates that the psychological modes of thinking have penetrated into France, also. Nothing essentially beyond Mourgue and others is presented, and the book is primarily a reference for specialists in this country. SAM PARKER

Clinical Laboratory Methods and Diagnosis. By R. B. H. Gradwohl, M.D. Quarto of 1028 pages, illustrated. St. Louis, C. V. Mosby Company, 1935. Cloth, \$8.50.

This book represents a collection of information which is very widely comprehensive in the field of the practice of laboratory methods and diagnosis. All phases of laboratory activity are discussed from the point of view of those whose medical home is in the laboratory.

Any attempt to describe the contents of the book in detail would require much more time and space than any reviewer has available. With the few criticisms that might be made such as the irritating frequency of the use of the personal pronoun and the omission of methods for the determination of cholesterol esters and the failure to include a description of bone marrow puncture, the book as a whole is an admirable

It is profusely, aptly and well illustrated. It should prove of great value especially to the laboratory man, as well as to anyone interested in any field of medicine.

MAX LEDERER

Aids to Ophthalmology. By N. Bishop Harman, M.A. Eighth edition 16mo of 242 pages, illustrated. Baltimore, William Wood & Company, 1935. Cloth, \$1.25.

This compend on ophthalmology is now in its 8th edition. While it is comprehensive for the needs of the medical student, it fails in providing certain indispensable features to be found in such popular books as May's, namely, vivid illustrations, and a more personal approach. Nevertheless, as a supplement to a course on that subject it is splendid.

The author is well known for his ingenious contributions and methods, which are illustrated throughout the text. He disapproves of lachrymal probing as a means of overcoming a stricture; but only for the purpose of diagnosis. He also counsels the operator not to disturb a ring of rust on the cornea after removing a piece of steel or iron. These and many other points from such an outstanding authority as Harman will arrest the reader's attention.

EMANUEL KRIMSKY

The Surgical Clinics of North America. Volume 15, number 3, June, 1935. (Chicago Number.) Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues). Cloth, \$16.00; Paper, \$12.00.

This, the Chicago issue of the Clinics, is devoted largely to traumatic surgery though abdominal and gynecological subjects are also treated. Most of Chicago's outstanding surgeons have contributed to this number creating an interesting and intensely practical volume. Geo. Webb

The International Medical Annual. A Year Book of Treatment and Practitioner's Index. Edited by H. Letheby Tidy, M.D. & A. Rendle Short, M.D. Octavo of 522 pages, illustrated. Baltimore, William Wood & Company, 1935. Cloth, \$6.00.

In rambling through a yearbook on medical reports, the reader is constantly confronted with a maze of confusing and contradictory reports, as well as some empirical and scientific data. Out of this morass he must exercise ingenuity in separating the chaff from the wheat. While medical progress is not a steady evolutionary process, these numerous ebbs and flows which constitute seemingly unimportant contributions, are, in the final analysis, indispensable in keeping medicine alive and in serving as harbingers of something more significant.

And so, this annual does not offer new discoveries of outstanding promise, but mainly a stock-taking of some of the things we have learned to accept complacently.

For example: 1. Noguchi's "discovery" of a germ of Trachoma is refuted.

2. Active immunization against scarlet fever cannot be assured.

3. Tonsillectomy is no protection against colds, otitis, rheumatism, or infective fevers. 4. Serum therapy is of no value in Pneu-

monia, except possibly in Type 1.

5. There is increasing opposition to BCG vaccine for tuberculosis.

6. The so-called cyclic vomiting attacks are not due to acidosis.

CHARLES B. TOWNS HOSPITAL

FOR THE EXCLUSIVE TREATMENT OF

ALCOHOLISM and DRUG ADDICTION

This hospital has specialized solely in addictions for over thirty years. Our experience has shown us that best results could not be obtained when associated with any other type of case. Its method of treatment has been fully described in the journal of the American Medical Association and other scientific literature. The treatment is a hospital procedure and provides a definite means of eliminating the craving and the toxic products of alcohol and drugs. Emphasizing the after care and with appreciation of the seriousness of the alcoholic problem we devote the convalescent period to minimizing the possibility of relapse. In the classification of the City of New York hospitals this institution has been granted a special license by the Commissioner of Hospitals for the exclusive treatment of alcoholic and drug addiction.

Education's Three-Base Hit

Life has three bases—mind, body and character-and the man whose life is built on only one of them has only got to first base, and no ball game in the world was ever won by players who could not get beyond first. Yet our public schools are full of boys and girls who are patted on the back and held up to public praise for a one-sided, a one-base, development.

"See that girl? She took the prize in advanced algebra!" "That boy is a wonder in the high hurdles!" "That one has a beautiful character!" Fine, but they are one-base hitters. They must learn to reach second and third or they will never score. A sharp drive between the bases or over the shortstop's head will put you on first, but it is not enough.

That is exactly the situation that the private school understands. The girl who is a star in algebra needs physical and cultural training to fit her to be a fine, splendid woman. The high-hurdler will find that in the hig world there is not much call for running and jumping. The boy or girl of fine character must have health and brains, too, or fall short of success.

The very day when your boy or girl enters a fine private school the teaching staff starts to size up and analyze his or her good qualities and weaknesses, and plan to make good what is lacking. The athletic instructor, of course, wants to develop his best athletes into winning teams, but he also looks carefully after the physical development of the weakest boy in the gym. Character-building, too, is cultivated in the private school in a way that the public school never even attempts.

In short, the private school makes threebase hitters, and it is a pretty safe bet that if the youngsters get to third, a big percentage will make a winning sprint to the home plate of success.

"Stone Walls Do Not a Prison Make—Nor Iron Bars a Cage"

Winter is a jailer who shuts us all in from the fullest vitamin D value of sunlight. The baby becomes virtually a prisoner, in several senses. First of all, meteorologic observations prove that winter sunshine in most sections of the country averages 10 to 50 per cent less than summer sunshine. Secondly, the quality of the available sunshine is inferior due to the shorter distance of the sun from the earth altering the angle of the sun's rays. Again, the hour of the day has an important bearing. At 8 30 AM there is an average loss of over 31%, and at 3 30 PM, over 21%.

Furthermore, at this season, the mother is likely to bundle her baby to keep it warm, shutting out the sun from Baby's skin, and in turning the carriage away from the wind, she may also turn the child's face away from the sun.

child's face away from the sun

Map Out Your New York Convention Stay

To enjoy your coming Convention to the utmost, map out your days and evenings and thus obtain the greatest use of available time.

No matter how many times a visitor to the great metropolis has been coming, there is always the prospect of seeing new things New York is

constantly changing. This is as true of downtown New York as it is of the East Side, West

Side, Fifth Avenue or Broadway.

The shade of the venturesome Henry Hudson on viewing the roof tops of Manhattan in 1936 would exclaim indignantly, "It isn't so, I don't believe it." If he should slip into the observation tower of the Empire State Building, 1,040 feet above scintillating Manhattan at night, a wisp of cloud at his elbow, or if he should stroll about the roof of Rockefeller Center not far distant, he would dismiss it all as a fantastic trick of an overwrought imagination. And so it would seem, and so it does seem at times even in this day and age of great dreams realized.

During the early part of the Dutch occupation, Wall Street separated the settlement from a wilderness to the north. The name of this street was derived from the wooden wall extending from river to river as a cattle guard and a protection against wild animals and Indians. Much later bears were given the freedom of the street, although this freedom is now somewhat restrained. In the settle-

ment below Wall Street, cow paths formed the regular thoroughfares and are still trace-

able to this day.

This is the tip of the area that has become the most important and fascinating city on earth, a city wherein millions reside on property that is worth fabulous billions as compared with the four and twenty dollars worth of trinkets that satisfied the original owners.

Instead of the frail craft that brought Hendrick from the old world, incredible floating palaces now sweep in from the Atlantic sea lanes and tie up casually and as a matter of course at piers a thousand feet long.

Upon the solid rock that is Manhattan's

(Continued from page xxxiii)

easy chair, a city has been built with spires that pierce the clouds—when there are any clouds to pierce. A city of countless wonders, to which the civilized world has contributed and whose attractions are so great that they draw visitors from all points of the compass time and time again.

Perhaps the finest accommodations anywhere are provided by scores of splendid hotels. The leading establishments of the city represent an investment of over three hundred millions of dollars. There are good accommodations to fit any pocketbook. oldest hotel in Manhattan is far downtown at Broad and Pearl streets. Fraunce's Tavern, opened in 1762, is one of the links with Old New York and has the distinction of being the only building in New York City to have been struck by a cannonball fired by an enemy. The best known hotels today are largely in mid-Manhattan. Hotels marched northward with the growth of the city and naturally so for more and more are they the centers of Metropolitan life.

Where Fort Amsterdam originally was built, now stands the Custom House. Bowling Green, Battery Park, and the Aquarium will be found unchanged to the returning traveler but not many pieces of property have escaped the tidal wave of change that swept across the nearby financial district. Towering skyscrapers give an appearance of theatricalism to Wall and Broad streets. When financial structures were piling, buildings in keeping were erected. Besides J. P. Morgan & Company's well known building at 23 Wall street, little remains of the street of ten years ago save the National City Bank and a very few lesser known houses. Trinity Church and the old cemetery where Revolutionary heroes are buried, are now hemmed in by mountainous monuments to business. And at the foot of the street from a recently constructed sea ramp, hydroplanes speed business men to their suburban estates and in summer to resorts normally hours way.

While Wall street and the Stock Exchange have received a lot of the nation's attention in recent years, the visitor to lower Manhattan is really more interested in the "stock" at the Aquarium. This unique place was formerly Castle Garden, famed for the millions of emigrants who passed through. Originally it was a fort, and later used for entertainment. Here many distinguished visitors to America were landed.

Between lower Manhattan and the mid-town section, lie innumerable points of interest. This area, too, emphasizes the saying that

(Continued on page xxxv)

(Continued from page xxxiv)

there are ten thousand New Yorks, depending upon the individual's viewpoint and personal interest. Scores of markets on East Side and West Side receive and dispense the daily provender for millions of hungry mouths. Here are located the Ghetto, Chinatown, Greenwich Village, and other distinct sections each a world in itself.

The East Side continues to excite the visitor's interest though not as vividly as it once did Chinatown is no longer a hot-bed of vice and crime, and no longer attracts the thrill seeker, but its quaint buildings, crooked streets, and strangely foreign populace will commue to draw even the calloused New Yorker to its environs. But, sally, the old Bowery without a song to perpetuate it would have passed into oblivion years ago. It belongs to a bygone day

Coming uptown, it is doubtful if any two points of interest in New York today arouse more general interest than Rockefeller Center and the Empire State Building. The elevated highway on the West Side, the George Washington Bridge, the Holland Tunnels, the Museums, Zoos, Subways, etc., will always excite wonder but no mitter what the visitor does in New York he invariably takes a turn through Rockefeller Center and never forgets to view the entire vicinity from Al Smith's Empire State tower.

Naturally, the business of the Convention is of first importance, but there will be some liesure moments when wasting precious time set aside for entertainment should be avoided. So much is always readily available that a visitor's problem is never one of anything but choice, and with so much to cloose from, some planning is necessary.

In addition to other features, the Waldorf-Astoria your Convention Headquarters, main time provisions for motor service, has special arrangements whereby pitrons may use near-by country clubs and the unusual "About the City Bureau" providing accredited guides, compations chaperons, and shoppers, as well as information on where to go and what to see There is also an office of Thomas Cook & Son for the benefit of travelers, and a Theatre Ticket Agency for your convenience

casts arranged by the BBC, in cooperation with the Cunard White Star Line.

Many parts of the ship, including even the crow's-nest, will be wired for microphones. It is proposed to describe, both from the ship and shore, the departure from Southampton and the arrival at New York.

On the second night out, listeners may be taken on a 45-minute tour of the ship, and each night it is planned to include a short flash in the news bulletin.

Good Will Tour by Hotel Man

Mr. Max Blouet, known to many people who have had the pleasure of a stay at the famous Hotel George V in Paris, is at present

on a good will tour of the United States and Canada.

The Hotel George V of Paris is the "Waldorf-Astoria" of France and a popular hostelry for distinguished visitors from America as well as the rest of the World

Mr. Blouet plans to visit Boston, Montreal, Toronto, Detroit, Chicago, Cincinnati, Pittsburgh, Washington, Norfolk, Baltimore, Philadelphia, and New York.

A Pleasant Way to Pleasure Islands

The Bermuda Hotels, Incorporated, and the American Airlines, Inc., announce a new way to reach Bermuda—by plane and steamer.

"The gangplank," they tell us, "is only a few hours away—when you fly. Say goodbye to dreary Winter and . . . presto! . . . you're aboard ship to where life, warmth and sunshine will fill your days."

Via American Airlines, vacation begins when you step aboard your plane to spend a few pleasant hours in the blue sky. If you're sailing tomorrow, you spend the night in New York instead of en route.

If you haven't flown before, you'll enjoy your trip on the largest airline in the United States. American Airlines, Inc., flies 6,850 miles of route connecting 57 cities in 22 states, directly serving more than 25,000,000 people, and has carried more passengers (some 700,000) than any other airline.

Round trip from Buffalo to New York is less than \$40 and the time required to bring you to New York is an hour and 34 minutes

Information on American Airline service from other cities may be had from your local travel agent, as well as sailing dates for steamers to Bermuda

Red Star Liners Reconditioned for Season's Service

As announced by John J. Dwyer, Passenger Traffic Manager of the Red Star and Arnold Bernstein Lines, advance bookings and inquiries on European travel for Spring and Summer point to the biggest season of travel in 1936 than in many years.

To adequately handle this increased business the steamers Westerland and Pennland have been completely rearranged and renovated from stem to stern. Staterooms, halls, and public rooms have been refurnished and improved from a standpoint of luxury and comfort

Hotel WOODSTOCK

127 WEST 43RD STREET
Just East of Broadway
UNDER KNOTT MANAGEMENT

(Continued from tage xxxvi)

Formerly carrying 1,400 passengers, the new arrangement calls for a maximum capacity of 565 travelers of tourist class, each accordingly having the run of the ship.

Other changes are rearrangement of the spacious sports decks, making room for additional outdoor games; enlarging the swimming pools, adding a rifle range, trap shooting range, and a miniature golf course.

Because of the increased demand by travelers who want to take their motor cars abroad with them, the ship garage on both steamers has been enlarged and so arranged that cars can be unloaded and serviced for the land journey within a few minutes after the steamers reach their destinations.

Discussing the seasonal outlook, Mr. Dwyer remarked, "It is really surprising the number of people who are not only booking passage abroad for themselves but for their automobiles as well. It is becoming the modern, comfortable and convenient method of travel, and with American trained mechanics and English speaking attendants to be found on every European road, the service and refueling stations on the Continent today are about as in the United States. For those planning budget trips, we have many planned trips for motor parties, which can be purchased here before sailing, complete in every detail even so far as to caring for the supply of gas and oil needed during the trips through the various countries."

A Gain in Florida Travel

Stating that "pleasure travel is one of the best indices of business conditions," Mr. S. B. Murdock, G. P. A. of the Seaboard Air Line Railway, points encouragingly to a 42 per cent increase over last year in travel on the Orange Blossom Special The Southern States Special and the New York-Florida Limited, covering the same route as the "Blossom," are close seconds in the almost unprecedented travel gain which Mr. Murdock says is indicative of general business gain.

"Business travel, on the other hand," he adds, "may maintain a fairly high level even in bad times. Firms redouble sales effort and there is a constant shifting of population in the search for new opportunities and for

employment,

"But present record travel on our trains is predominantly travel for pleasure. It means that thousands of people are again able to take vacations in Winter; to spend money without the expectation of any return except what the economists call 'psychic income,' which means the resulting satisfaction and pleasure. So great

(Continued from tage xxxix)

an increase in number of passengers carried in one season by the Orange Blossom Special is thus an important gauge of the improvement in business conditions, and I do not believe the peak of the season has yet been reached.

"Besides rapidly returning prosperity, other factors in the record travel on this famous train are: low rail fares with liberal stop-over privileges, so that without any additional fare one may visit both coasts of Florida and also the famous mid-South resorts of Camden, Sea Island, Southern Pines, and Pinehurst. And if there are at least two pullman passengers in the party, one may take a car along at the cost of only one additional passenger fare."

Mr. Murdock also pointed out as factors, the air-conditioning feature for comfort, and the quality of food and service which form so much a part of the popularity of the "Blossom."

Atlantic City's Marine Activities

Atlantic City has prepared for a definite increase in the various branches of marine activities this summer. For the past year both federal and local governments have been working on projects to aid yachting and deep sea fishing, and within the next few weeks, the projects will be complete for the influx of the resort's spring and summer visitors.

Atlantic City will have a channel 250 feet wide and deep enough to accommodate shipping with an average of 17 feet at mean low water. It will extend 4,700 feet from the Inlet to its termination outside, following a south-southwest magnetic course. Skippers, both experienced and amateur, will have no difficulty in navigating their boats into the port now that the channel has been dredged. This dredging, which is the work of the federal government, will be completed at a cost of \$184,000 and has been in progress for nearly a year.

The fishing bank project, as proposed by the Atlantic City Chamber of Commerce, is set for a hearing with the War Department. The Chamber of Commerce is seeking the approval of the Department to deposit debris over the ocean floor in an area one mile wide, four miles long and about 11 miles from the coast. The purpose of the bank is to collect marine growth and attract fish for hand-line fishing.

The Tuna Club, a local organization formed for the purpose of aiding the resort's guestfisherman to catch the most fish with the least effort and expense, has a membership of over 200 enthusiastic workers meeting regularly in order to have their program in readiness for the throngs who will take advantage of the Club's service.

J. 17. 18 1 --

(Continued from page xli) Travel Brevities

Among Traveling Colleagues we find Dr. Hans Friess of New York sailing on the "Monarch of Bermuda." Dr. and Mrs. Horace K. Sowles, and Dr. and Mrs. Homer C. Sowles, of Boston, sailed on the "Queen of Bermuda." All were destined for a Bermuda rest.

In Bermuda we note the following doctors enjoying the Hamilton Hotel-Dr. B. D. Thorpe of Newport, N. H.; Dr. P. H. Gilbelhous of Bayside, L. I.; Dr. Eugene M. Blake, New Haven, Conn. and Dr. A. E. Ogden, Trenton, N. J.

To Understand England, a traveler must have some historic sense; he must see in tradition something more than a ludicrous or sentimental survival and in the monuments of the past something more than the husks of departed glories.

THERE are no fewer than 360 characters in The Pickwick Papers by Dickens, and twentytwo inns are mentioned by name. What a travel man!

THE NEW MOTORLINER Batory, sistership of the Pilsudski and second new trans-Atlantic liner to be built by Poland since the nation regained its independence, will leave Gdynia on her maiden trip on May 18th and arrive in New York on May 27th. On its return maiden voyage, the Batory will leave New York on June 2nd. Launched last July 3rd, the new liner is nearing completion at the Monfalcone Shipyards in Trieste, Italy. It will join the Pilsudski on the New York-Halifax-Copenhagen-Gdynia run, twenty round-trip trans-Atlantic crossings in 1936.

Among American Universities which are arranging tours of their students to include the Olympic Games in Germany this year are Notre Dame, Virginia and Maryland, according to Thos. Cook & Son-Wagons-Lits Inc., who have been appointed official transportation agents in handling details of the trips. The Notre Dame group, according to Cook's, will sail on the Normandie from New York on July 15th. The groups from the Universities of Virginia and Maryland will sail on the Bremen on July 17th. In addition to attending the Olympic Games, the tours will include the principal cities of England, France, Germany, Holland, Italy and other European countries.

Over Ten Thousand passengers were carried by 13 steamers on the special cruises over Christmas and New Year's. Some kind of a new record set for this period.

FOR

GENERATIONS

Great Western

MERITS THE CONFIDENCE OF THE PROFESSION

Some of the reasons for its continued acceptance are:

- Quality and Purity.
 Great Western Champagnes are made by the true French method of slow fermentation in the bottle, taking years of time.
- 2. Only American Champagne to win medals in Paris, Brussels and Vienna.
- 3. Because it is made in America you don't pay for import duty, ocean freight, etc.

Good stores everywhere are ready to serve you. Write for our booklet, "The Art of Serving Wines and Champagnes." Address Dept. NYM-3. Pleasant Valley Wine Co., Rheims, N. Y.

NEXT ANNUAL MEETING, NEW YORK CITY, APRIL 27-28-29, 1936

THE ALKALINE EFFECT OF MILK

HOODS containing salts of the akaline metals generally exert an alkaline effect in the body. Because of its calcium and potassium salts content, milk is definitely in this class. These salts are largely "burned" in the body following the ingestion of milk. In this process of reduction, the original acid parts of the salts are eliminated in the breath . . . the metals remain as an alkaline ash for neutralizing acidic products in the blood. Increased ingestion of milk would tend, therefore, to increase the alkaline ash content (or alkaline reserve) of the blood.

THE STATE OF NEW YORK

Makes Milk an even Better Food

A quart of milk per day covers the calcium needs of even a rapidly growing infant. A pint takes care of the adult's. Milk is also a rich source of phosphorus.

Every quart of Vitex* Vitamin D Milk contains 400 U.S.P. Vitamin D units—the Vitamin D equivalent of 1½ teaspoonfuls of U.S.P. Cod Liver Oil.

Vitex is the actual Vitamin D of Cod Liver Oil which when added to pure milk creates a wholesome and convenient combination a "better" milk.

* Vitamin D Concentrate developed in the laboratories of and controlled by Columbia University.

Principal licensees in New York State and adjacent communities.

Maintain Mineral Alkali Balance

WITH

Kalak

Hypertonic-Alkaline-Carbonated-Not Laxative

The years of experience with physicians who have used Kalak show that the use of a formula containing calcium, magnesium, sodium and potassium salts represents a correctly balanced solution. This is Kalak which, as such, aids in maintaining a balanced base reserve.

How Alkaline Is Kalak?

One liter of Kalak requires more than 700 cc. N/10 HCl for neutralization of bases present as bicarbonates. Kalak is capable of neutralizing approximately three-quarters its volume of decinormal hydrochloric acid.

DECONGESTIVE SOOTHING

ZEO-SYNEPHRIZI HYDROCHLORIDE

(levo-meta-methylaminoethanolphenol hydrochloride)

In relieving the symptom of nasal congestion, the valuable vaso-constrictor, Neo-Synephrin Hydrochloride, offers these advantages:

Active on repeated application

More sustained action than epinephrine

Less toxic in therapeutic doses than epinephrine or ephedrine

No sting at point of application

The absence of irritation and sting, low toxicity, little nervousness or palpitation, combined with prompt and prolonged effect are some of the reasons for the clinical success of Neo-Synephrin

Supplied in these contenient dosage forms:

WHY CAMP SUPPORTS ARE SCIENTIFICALLY DESIGNED

HE Camp designing staff — with a combined experience of many years in the surgical support field—is constantly endeavoring to render in Camp garments the objectives of various groups of specialists consulted, as well as professional suggestions relayed by Camp nurses detailing all over the world and by Camp dealers.

From the eastern seaboard three years ago and a little later from the West and Midwest came this suggestion from obstetricians: the desirability of a diagonal pull, instead of straight around attachments, in a garment designed to support the abdominal walls without disturbing the relation-ship of the fetus to the pelvis. To effect this abdominal support, and at the same time to provide proper back support, was a task involving considerable difficulties. However, approximately twelve months later-after numerous conferences, many adjustments and trial by various pregnant patients—a new series of prenatal supports was completed, prenatal supports with a diagonal pull, proved by X-ray to support properly the abdominal walls without constriction at

any point. A comparable situation arose with a number of different internists. The desirability of a garment to fit snugly - without discomfort - over thin, protruding hip bones and yet to hold the abdominal organs as high as possible, was obvious from requests by physicians who had prescribed and found wanting in these respects many viscerop-tosis garments. To provide such a garment involved the manufacture of specially made material pliable enough to fit like a hood over the crest of the ilium and sufficiently firm to support the abdominal organs. Only after two years of collaboration and painstaking investigation was there ready for distribution a series of such garments.

S. H. CAMP & COMPANY, JACKSON, MICH. Manufacturers

Camp supports are scientifically designed.

This is the designing room at the Camp factory—a veritable melting pot of professional desires and design possibilities. This is why

FOR A PRACTICAL RANGE OF X-RAY DIAGNOSIS IN OFFICE PRACTICE

Physicians Acclaim Quality of Work Produced with G-E Model "D" Oil-Immersed Shock Proof X-Ray Unit

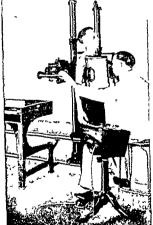

The Model "D" Unit mobile type can be used in any part of the office or building. This view shows how the office examination couch may be utilized for radiography with the unit.

 In the final analysis, an x-ray unit must be judged by the quality of results obtained, for the simple reason that diagnosis is based on what it enables you to visualize in the radiograph or the fluoroscopic screen.

The Model "D" Unit has become widely popular in office practice because it offers a practical range of diagnostic service, in the most compact form, with the utmost flexibility of application, simplicity of operation, and consistent performance. All this in addition to complete safety against high voltage shock, and a resulting quality of work in which hundreds of Model "D" users take justifiable pride.

Not until you have thoroughly investigated the possibilities of this apparatus can you really appreciate its value in routine office practice. Address Dept. A53, for full details, including the nominal price and convenient terms of payment which place it within your means.

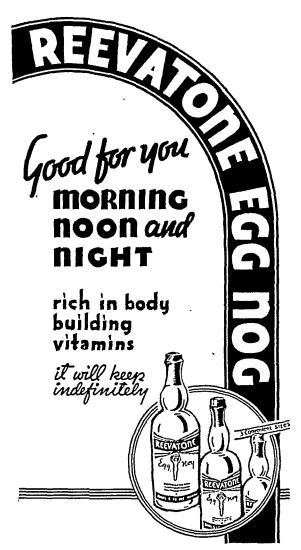

This is the "DRF" Unit, a combination of the Model "D" unh an x-ray to his family

Presents over Forty Delightful Recipes

For a perfect egg nog or milk shake dilute Reevatone with milk to desired proportions.

Can also be diluted with hot milk for a night cap or cold milk as a refreshment—dash of Angostura bitters and top with nutmeg.

Double mellow and very fresh-mixes readily with cognac, gin, rum, whiskey, wine, or coffee.

Drink Reevatone straight, from the bottle, or employ it as an excellent liquor accessory and mixer for numerous concoctions.

Reevatone is perfect for sauces, delightful on fruits, puddings, ice cream and other desserts.

Sign-Posts that Show the Roads

When you travel over highways in constantly changing territories, you watch the signs that guide you safely and surely to your destination.

Advertisements are the guide-posts along the "buy-ways" of products and services in every profession, business, or trade. Improvements and new discoveries are being pointed out by advertisements in this constantly changing world of ours. Shortcuts and improved roads are learned through advertisements as surely as through scientific articles. And each plays a part in your "journey."

In this issue of the New YORK STATE JOURNAL OF MEDICINE you will find over one hundred advertisers trying to help you on your way. Take the time to read their messages.

Presents over Forty Delightful Recipes

For a perfect egg nog or milk shake dilute Reevatone with milk to desired proportions. Can also be diluted with hot milk for a

dash of Angostura bitters and top with nutmeg.

Double mellow and very fresh-mixes readily with cognac, gin, rum, whiskey, wine, or coffee.

Drink Reevatone straight, from the bottle, or employ it as an excellent liquor accessory and mixer for numerous concoctions.

Reevatone is perfect for sauces, delightful on fruits, puddings, ice cream and other desserts.

For the prevention and treatment of staphylococcic infections

STAPHYLOCOCCUS TOXOID **Bederle**

STAPHYLOCOCCUS TOXOID has assumed an importance in the field of biologic therapy which merits recognition.

With its aid physicians are successfully treating recurrent and chronic staphylococcic infections which were formerly considered to be intractable.

Murray (Lancet, 1935,1,303) reports the following results of its use:

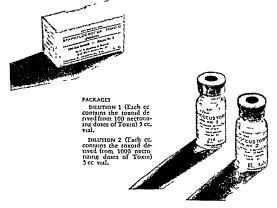

Condition Treated	Reco	overed	Impro	vement	Slight	or No Benefit
Acne	3	cases	21	cases	6	cases
Blepharitis	8	"	6	**	1	"
Furunculosis	25	"	14	"	-	"
Carbuncles	3	**	1	"		"
Others	12	"	14	"	2	**
	_					
Total	51		56		9	

C. E. Dolman (Lancet, Feb. 9, 1935,306) reported successful results in 72 out of 81 cases of intractable staphylococcic infections with a series of injections of Staphylococcus Toxoid.

Each preparation of Staphylococcus Toxoid *Lederle* is tested for antigenic potency before release.

... and TAKE SOME EXERCISE?

"Exercise" should mean something more to physicians than merely telling a patient to take up some form of "sport," to go to "a gymnasium," or to invest in some sort of a "mechanical exerciser." The very fact that supervision alone is vitally important even to persons not pathological subjects, is sufficient reason to give more than a perfunctory counseling when exercise is indicated, and to have some definite knowledge of "what," "where," and "how much" would be most beneficial in each case.

One thing you should know about *The Health Roof* is that it should not be misconstrued as "a gymnasium" intended for a purpose of developing athletes or building brawn—it is primarily and exclusively equipped to aid, under proper supervision, in restoring and maintaining physical fitness for the normal life of the average man and woman.

DO YOU LIKE GOOD CREAM CHEESE?

The Age-old Problem-the Diet

The doctors of the Classical Era appreciated and practiced "preventive medicine," and dieting became a fine art in Rome, Greece, and Egypt. Great medical writers published excellent books on dieting, and advocated such practice as a preventive measure and as a preparative in illness or disease where nature is expected to make a cure. Strains on kidneys, liver, and other organs through excessive protein waste products from overfeeding and want of exercise, was unknown to them; although experience had revealed to them that people who ate moderately and worked hard

enjoyed far better health than those who ate too much and did no work.

Centuries have passed and civilization has not cured a human failing to over-indulge and to neglect. Moreover, there has been an increased squeamishness about foods. A taste has been cultivated for dishes that flatter the olfactory and gustatory senses, rather than for those more beneficial but less inviting.

So the modern physician's problems on diet becomes in addition to right selection of beneficial and easily assimilable foods, one of choosing such as are well prepared, tasteful, and convenient to serve.

They Make Kemp's SUN-RAYED

-the Original Pure Tomato Juice

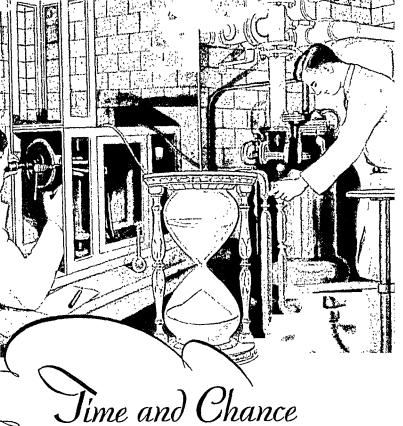

Three brothers make Kemp's Sun-Rayed -the original, vitamin-certified, nonseparating, undiluted tomato juice. They

pioneered the production of pure tomato juice which physicians can recommend with confidence.... When they introduced Sun-Rayed in 1929-after 4 years' research-it was intended for infant feeding. And

now that it has become nationally preferred as a fruit juice drink, the same original precautions taken to insure its nutritional values have been strictly adhered to. Made by exclusive process (U. S. Pat. 1746657)... At all food stores-independent and chains.

Write for free copy of Steenbock Report on Feeding Tests, J-36, The Sun-Rayed Company, Frankfort, Indiana.

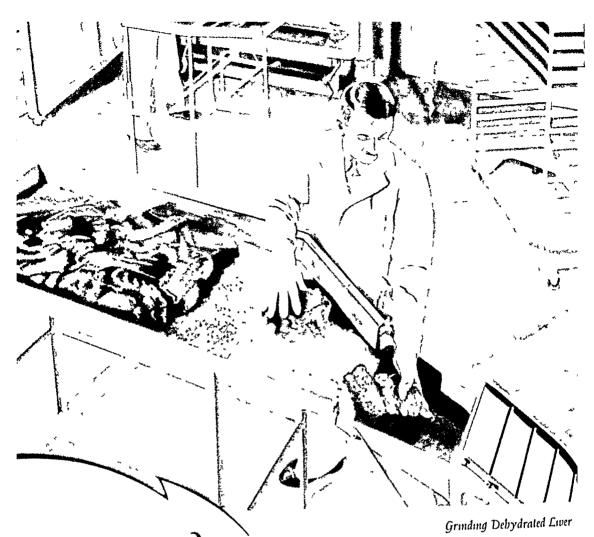

Time and chance play an important role in discoinvention. TEN MILKS for INFANT FEEDING

but KARO

is a UNIVERSAL MODIFIER

	Milks	. Indication
1	Whole Milk	Normal Feeding
2	Skimmed Milk	Infection Vomiting Diarrhea
3	Top Milk	Malnutrition Constipation
4	Soft Curd Milk	Intolerance Indigestion
5	Evaporated Milk	Prematurity Marasmus Eczema
6	Dried Milk	Intolerance Allergy Travelling
7	Acid Milk	Marasmus Diarrhea Celiac Disease
8	Protein Milk	Diarrhea Celiac Disease
9	Butter-Flour Mixture	Marasmus
10	Goat's Milk	Allergy

ARTIFICIAL feeding consists of cow's milk modified to the degree of adequacy of breast milk. The types of formulæ devised appear different—but successful mixtures contain approximately the same distribution in protein, carbohydrate and fat. Two-thirds of the total calories are supplied in milk and one-third in added carbohydrate. The formulæ contain 10-20% of the calories in protein, 20-30% in fat and 50-70% in carbohydrate.

Most infants tolerate whole milk. But those with irritable gastro-intestinal tracts, limited digestive capacities or allergic sensitivities, require milk adapted to their low tolerance. As a result, milk has been altered chemically in various ways to make it especially suitable for each type of infant feeding problem. The adjacent column reveals indications for various milks.

But the ten milks available for infant feeding can be safely modified with Karo. It is adapted to every type of formula devised. Karo consists of dextrins, maltose and dextrose (with a small percentage of sucrose added for flavor) practically free from protein, starch and minerals. Karo is a non-allergic carbohydrate, not readily fermentable, well tolerated, readily digested, effectively utilized and economical for both the baby and the budget.

No. 6

THE ABUSE OF CESAREAN SECTION

EDWIN G LANGROCK, MD, New York City

At the end of pregnancy the uterus which is normally a small almost solid organ two and one-half inches long, has been converted into a thin-walled muscular sac almost thirteen inches long, ten inches wide, and nine inches deep, capable of containing the fetus, the placenta, and a large quantity of amniotic fluid Its capacity has increased 519 times and it weighs about two pounds, as against one ounce which is its weight in the virginal condition In cesarean section one opens this hollow, muscular viscus, which is continuous with the vagina, the lower end of which is always contaminated, and takes from it, through the peritoneal cavity, (1) a baby, covered with more or less vernix caseosa (2) an umbilical cord (3) a placenta-weighing one sixth as much as the baby (4) membranes (5) a varying amount of amniotic fluid-sometimes mixed with meconium (6) blood, fluid and clotted, from the placental site and uterine sinuses

In no other operation in abdominal surgery is the peritoneum thus exposed. It is expecting much of the peritoneum to have it withstand such a procedure without infection.

Patients usually die from shock due to trauma and hemorrhage or from peritomits due to infection. Such an abdominal operation must be hazardous even when done under ideal conditions by the most skillful operator.

The low cervical cesarean section or laparo trachelotomy as it is called by De Lee, its chief exponent, is much safer than the classical operation but even it has a high maternal mortality

Lull states "that unless one is thoroughly trained the low operation is much more likely to be fatal from shock or hemorrhage". He states also "that the average maternal

mortality throughout the country in cesarean section is 67 per cent"

Colum in an analysis of 220 cases of abdominal cessive in section noted a maternal mortality of 55 per cent—the number of deaths going from zero to eleven per cent. In 818 per cent of these women the membranes had not ruptured at the time of operation. In this series the morbidity in the classical operation was forty one per cent and in the low cervical thirty eight per cent—very little difference.

Duchman³ in an analysis of 733 cases of cesarean section reports a maternal mortality of 3.4 per cent with morbidity of 43.8%

Gordon' reported a maternal mortality rate of 114 per cent in cases of breech presentation treated by cesarcan section De Lee5 comments on this by saying "a maternal mortality of 114 per cent for cesarean section should make us all pause and ask why"

O'Connor⁶ reported on 436 cestrean sections. His incidence was one in thirty—and the gross mortality was 46 per cent. In his group of classical sections the mortality was four per cent against 53 per cent in his low cervical sections. Fifteen per cent of his deaths occurred in clean, elective nontovic patients in good condition. His mortality in eclampsia was 20 per cent.

De Lee' in commenting on this report says "I must, however, warn against the growing mustes of a noble operation. The mortality from it in the United States is at least six per cent which is frightful, and something must be done about it. In some places the mortality is over ten per cent and we wonder if we have not wandered too far away from our old friend watchful expectancy. Also, where have the real obstetricians gone? As soon as the doctor is presented with a complicated knot in obstetrics to until, he simply cuts it."

The low cervical cesarean section is vaunted as being safe especially in suspiciously infected cases

Trillats⁸ writes on the dangers of the low cervical cesarean section in suspiciously

infected cases. He reports 110 cases of the low cervical cesarean section with a total maternal mortality of 7.2 per cent. In this series in even the cleanest cases, it was 3 per cent and in more potentially infected cases, as high as 28.5 per cent.

De Lee, the champion of the low cervical cesarean section, amazed at Lull's maternal mortality rate of 6.8 per cent comments on

these statistics as follows:

"In spite of these enormous mortality rates for cesarean section, the operation is being done often in the United States-too often." Of the report on the low cervical cesarean section, he says, 10 "these are terrific I learn from these mortality rates. . . . figures that even the low cesarcan section has a high mortality in infected cases and that perhaps we should fall back on our dishonored friend craniotomy—pity 'tis true."

There are many more statistics to show that abdominal cesarean section carries with it a high maternal mortality rate. Many series with a high mortality rate are not even reported and hundreds of scattered individual deaths never get into the literature.

Cesarean section has a much higher maternal mortality rate than we suppose even when the low cervical operation is done at the optimum time by the most skilled operator. It is evident that fewer cesarean sections should be performed, especially since far too many are being done for nonvalid indications. The commonest of these are:

1. Placenta previa. The conservative treatment of the simpler types of placenta previa gives a low maternal mortality rate. This treatment consists of the use of the modified De Ribes bag, packing, Braxton Hicks version, etc. Cesarcan section has a limited place in the treatment of placenta previa particularly of the central type in primiparae; but placenta previa is essentially a condition of multiparity and the central type is relatively infrequent. Cesarcan section is very rarely necessary in the great majority of the cases of placenta previa.

2. Accidental hemorrhage. That this complication, namely the premature separation of a normally implanted placenta is best treated by conservative means is exemplified by the report of Frederick C. Irving¹¹ of Harvard University of 269 cases. In the cases treated by cesarean section maternal mortality was 15.7 per cent. the cases of similar severity, treated conservatively the maternal mortality was 7.1 per cent—less than one-half. The tendency throughout the country is to do a cesarean section on any woman past the sixth month of pregnancy, the moment that she loses some blood.

There are rare cases of placenta previa and accidental hemorrhage in which cesarean section is indicated, but most of the patients with these two complications now being delivered by cesarean section could be treated more safely by conservative methods.

3. Eclampsia. In general surgery a patient with hypertension, acute nephritis, convulsions, and perhaps coma is considered the poorest risk for any operation. pregnancy such a patient is just as poor a surgical risk. The shock of cesarean section in an eclamptic patient even when done under local anesthesia, and the decreased resistance to infection which this patient has, practically preclude its use. Besides, the conservative treatment toxemia of pregnancy and eclampsia is conceded the world over to yield the best results of any so far. Cesarean section in toxemia of pregnancy or eclampsia is practically contraindicated.

4. Uterine inertia and rigid cervix. According to Edgar12 "the duration of the first stage of labor is variable. It may be as short as two hours and it may continue several days." The number of patients at present in whom the first stage is allowed to go on for several days, thereby escaping cesarean section, is very small. The cervix will almost always become fully dilated if you give it enough time. Patients with ineffectual pains, pains that are irregular in force and rate, will naturally have a longer first stage, but active treatment is not demanded when labor is slow as a result of such pains. With intelligent treatment they gradually improve in character, and finally bring about full cervical dilatation.

Uterine inertia with so-called rigid cervix is the excuse the attendant gives for doing a cesarean section. It is not a valid excuse because with careful management of the first stage, particularly with the use of morphine, scopolamine, sodium amytal, pento-barbital, nembutal, rectal analgesia, gas oxygen by inhalation, or the many other hypnotics and analgesics at our disposal today, it should not be necessary to do a cesarean section for so-called uterine inertia. This is particularly true in primiparae where the attendant instead of waiting patiently for the labor to progress cuts it short. The length of time per se that a patient is in labor is not an indication for any interference—certainly not for cesarean

5. Cephalopelvic disproportion. pelvic disproportion is the excuse for most of the unnecessary cesarean sections being

done today.

Cook13 in a recent article states that "feto-maternal disproportion is the most commonly encountered excuse for cesarean section. If it were not so tragic the truth of this situation would be laughable,"

Lull, in listing the indications for cesarean section says, "where the indication is listed as cephalopelvic disproportion there may be some instances where the imagina-

tion is stretched a trifle."

In cephalopelvic disproportion the indication for cesarean section is either absolute or relative. The absolute indication is where the baby can only be removed by cesarean section-that is, where the true conjugate diameter of the pelvis is five to six and one-half centimeters. From such a pelvis, or where similar disproportion exists, even a mutilated child cannot be born. Absolute disproportion is very rare and the indication for cesarean section is purely objective because there is no other way for the attendant to deliver the patient.

The indications in relative disproportion for cesarean section then are purely sub-That is, subjective with the attendant, simply because he makes up his mind that this patient must be delivered by cesarean section. The attendant's decision emanates from and depends upon his:

1. Obstetrical knowledge and experience or

from below.

2 Skill in delivery by the vaginal route or his lack thereof. 3. Courage and patience to wait and deliver

4. Willingness to sacrifice his time and strength in the interest of the patient.

If the attendant cannot correctly evaluate the status of the patient or if he has not the necessary ability to deliver her from below, he will immediately fice to cesarcan section. He thereby terminates a labor which could have been completed from below, and with much greater safety to the patient.

It is known that even patients with border line disproportion can generally be delivered from below. Often when we thought that cesarean section eventually be necessary we were surprised at the ease and facility with which the patient was delivered via the vaginal route.

Relative cephalopelvic disproportion. whether it exists or not, is frequently an excuse for doing a cesarean section. If the fetus was dead in any one of these particular patients the attendant would necessarily deliver her from below.

6. Heart Disease. Several facts are remarkable about heart disease in pregnancy

and labor, namely that:

1. These patients frequently have short easy

2. Patients with moderate decompensation usually stand the ordeal of labor very well.

3. Even with enlargement of abdomen present at full term, they take general anesthetics well.

Therefore cesarean section is rarely indicated in labor complicated by heart disease. It is never indicated solely because the

patient has an organic murmur.

7. Cesarean section in the interest of the The recent criticism of obstetrical practice in this country has not been aimed at our fetal mortality but rather at our maternal mortality. While admitting a better fetal mortality rate in delivery by cesarean section, I am certain that we would not be criticized for a slight additional fetal mortality in exchange for a lower maternal In the rare instance where a mortality. living baby must be had at almost any cost, it is justifiable to subject the mother to the added risk of cesarean section, but the attendant should not rush into cesarean section at the first sign of fetal distressnor must he do a cesarean section because of the odium that a fetal death would bring upon himself.

It is important that the baby be in prime condition when the abdominal incision is Although it may seem incredible, too many children born following a cesarean section are either dead when extracted or

live only a few hours,

It must not be assumed that most of the babies, now saved by cesarean section, would not have been saved had they been born via the vagina. The high fetal mortality in reported series of cesarean sections is

remarkable.

8. Malpresentation or malposition of the fetus. It is inconceivable that anyone would do a cesarean section for malpresentation or malposition—per se, at the onset of or during labor. Nevertheless many cesarean sections are done because of a malpresentation or a malposition such as occiputoposterior position, especially if the labor is not progressing to suit the attendant.

In breech presentation, especially primiparae, the fetal mortality is about three or four times as great as in vertex presentation but even in border line pelves the baby can always be extracted from below even if on rare occasions the aftercoming head must be crushed. Breech presentation per se even in primiparae is not an indication for cesarean section.

9. Nonengagement of the fetal head at beginning of labor, especially

primiparae.

In primiparae the fetal head is usually engaged in or even through the pelvic inlet about two weeks before the onset of labor if there is no cephalopelvic disproportion, If however the head is not engaged at the

onset of labor it does not signify that cephalopelvic disproportion exists nor does it indicate that the patient will not deliver herself easily from below. This is contrary however to the belief of many otherwise well-informed obstetricians. I wish to state that nonengagement of the fetal head at the onset of labor is *not* an indication for cesarean section.

10. Reluctance of attendant to make sacrifice of time and effort. The proper care of a patient in labor consumes more time than the care of any other medical or surgical patient. The obstetrician must be either in constant attendance or visit the patient at frequent intervals over a period of from two hours to several days. A great amount of time must be devoted, much effort expended and a great physical sacrifice made, especially in a long drawn out primiparous labor which may go through more than one night. A mid-forceps operation for persistent occiputo-posterior position with an episiotomy and its repair, and a trying third stage at the end of a forty-eight hour vigil is technically more difficult and physically more trying for the attendant than a cesarean section done two evenings Patients are being subjected to cesarean section because it is the quickest and easiest way out for the attendant. course a contributing excuse is found.

11. Monetary considerations. The doctor lives through thirty-six to seventy-two hours of labor with his patient and at the end of this time struggles through a difficult delivery from below. For this he receives a certain fee but he can spare himself the work and get a larger fee by doing an early cesarean section. The unscrupulous doctor chooses the latter method.

It is unfortunate that patients are willing to pay, and doctors are willing to demand a greater fee for a cesarean section than for a delivery from below. Of course just

the reverse should be true.

Craniotomy, internal podalic version, mid-forceps operations, cervical incisions, use of the De Ribes bag, and the like are becoming rarer and rarer obstetric procedures. They are being supplanted by cesarean section. In some of our larger hospitals a basiotribe no longer exists, and in others it has not been out of the instrument cabinet for several years.

The cesarean section urge has made us forget that patients can be delivered safely from below even if dystocia exists. Williams¹⁴ in his text book states that "in moderate degrees of pelvic contraction craniotomy if properly performed in

uninfected women is almost devoid of danger."

In Curtis' System of Obstetrics and Gynecology¹⁵ it is stated that "if no infection has occurred the risk of craniotomy should be scarcely more than forceps."

Shir¹⁶ reported 143 patients in which Duhrssen's incisions of the cervix were made. De Lee¹⁷ commented on this report by saying "when the incisions are made at the proper time they are without danger except in the rudest hands. Here is an instance where a skillful obstetrician can save many babies and mothers without resorting to cesarean section."

I have described a group of patients in whom unnecessary cesarean sections are being done. Some of these patients could have delivered themselves spontaneously, some could have been delivered from below, artificially but very easily. In many of the others the operations which I have just mentioned (craniotomy, mid-forceps,

etc.) were indicated.

The preponderance of cesarean sections done for nonvalid indications are done in primiparae. It is important to realize the condition in which the patient is left for her second pregnancy. The mortality and morbidity of cesarean section are not its only bad features; the fact that future cesarean sections will probably be necessary adds to its disadvantages. women must have a cesarean section done every time they become pregnant for no other reason than that they were delivered in this manner the first time. Had the first cesarean section been avoided, even at the expense of a dead baby, they could thereafter have had normal multiparous confinements. This is exemplified by the cesarean section which is done in a primipara for breech presentation.

Conclusions

The maternal mortality from cesarean sections in the United States is frightfully high. It is at least from six to ten per cent and probably higher because many bad series of cases are never published, and many scattered individual deaths never reported. The main cause of this high maternal mortality rate is not to be found in a lack of skill on the part of the operator, nor in the fact that the operation is done too late in labor, nor in the fact that the membranes have been ruptured

too long, nor in the fact that the patient was presumably infected Granting, however, that all these may be contributing causes, cesarean section still has a high mortality rate even when done on the cleanest patient, by the most skilled operator at the optimum time The main cause resides in the very nature of the procedure itself

It was brought out at the beginning of this article that such an operation must necessarily be a hazardous undertaking and therefore the only way that the number of deaths can be reduced is to perform fewer cesarean sections. There are patients being delivered by cesarean section for uterme inertia and cephalopelvic disproportion in whom there is really no reason whatsoever for doing this operation.

Even in the group in which relative disproportion exists most of the patients could be delivered from below of living babies, by one of the usual but now oldfashioned obstetric procedures having a maternal mortality rate almost nil. these cases it is true that an occasional baby would be lost, rather than an occa-

sional mother

An indication for cesarean section exists when during labor it becomes evident that major disproportion between passenger and passage is present; it also exists when, during labor, it becomes evident, due to a combination of factors, that a cesarean section would be safer than a delivery These two indications are relatively rare but they are the ones in which most mistakes are made. They are the ones that are most abused even by men whose intentions are honest

The conclusion that major disproportion exists can frequently be arrived at only after a full test of labor A full test of labor is a test of the second stage, not of the first stage; that is, a patient in whom the cervix has not been fully dilated for about two hours with the membranes ruptured, cannot be said to have had a test of labor.

The habit prevalent today of hastening to cesarean section as soon as any obstetric difficulty arises should be cured habit can only be cured when the attendant has sufficient experience to correctly evaluate the status of his patient, when the attendant makes his decision honestly,without regard to his personal convenience -and when the attendant has so perfected himself in obstetric operations that he feels just as competent in doing a vaginal delivery as he does in doing a cesarean section

To quote De Lee18 again "there is hardly an obstetric complication that has not been treated by cesarean section-indeed many men know of but one way out of a difficult obstetric situation and that is

cesarean section

When a patient is in labor, especially a primipara, the attendant should relegate the thought of cesarean section to the remotest corner of his mind, for he will then give her a real test of labor; whereas with cesarean section uppermost in his thoughts, knowing that the longer the labor is allowed to progress the more dangerous the cesarean section becomes, he cuts the test of labor short.

It is frequently too late to do a cesarean section safely; it is hardly ever too late to deliver safely from below. Cesarean section is usually done too early-before the patient has a chance at vaginal delivery.

Let us give patients solid conservative treatment This is safe and satisfactory. Let us carry out intelligent, watchful expectancy in labor. Let us acquire experience and skill in vaginal delivery, and these two will give us the courage to treat our patients conservatively throughout labor and to deliver them through the natural passage 515 PARK AVE.

TUBERCULOUS AND TUBERCULOID SKIN DISEASES Study of 240 Cases

TIMOTHY J. RIORDAN, M.D., New York City

Tuberculosis of the skin as well as tuberculosis of other organs is established definitely by the demonstration of the tubercle bacillus in smears or skin sections, by culture, and by animal inoculation. Important aids in confirming the diagnosis of tuberculosis are properly controlled skin tests and histopathologic studies of skin sections. The great amount of time necessary in examining material for tubercle bacilli and the great expense necessary in carrying out culture methods and animal inoculation limit the employment of these tests. The use of tuberculin skin tests is gaining favor, and possibly the conclusions of workers in this field may soon be generally accepted. Histopathologic study affords the clinician valuable aid in confirming his diagnosis.

In this paper the value and limitations of the histopathologic studies are considered in 240 cases divided into four classes which belong in the group of dermatoses classified under tuberculosis including tuberculids and the borderline diseases. They comprised about sixteen per cent of 1490 biopsies. It is noted that the interpretation in these cases conformed with the following statement which appears in all editions of *Pathologic Anatomy and Histology* by Delafield and Prudden:

In studying the reaction of living tissues to the tubercle bacillus it should always be borne in mind that while as a whole, the lesions produced are quite characteristic, there is still no one structural feature or combination of features of tubercles or tuberculous inflammation which is absolutely distinctive of the action of the bacillus.

In proposing the four classifications, the following basic concepts are admitted. The key to tuberculous tissue is the tubercle. Three types of tubercle are recognized.

1. A nodule consisting of an area of central cascation, an intermediate zone containing epithelioid cells and lymphocytes and possibly giant cells, and a peripheral zone of lymphocytes.

2. A nodule consisting of epithelioid cells, lymphocytes, and giant cells arranged so that the epithelioid cells predominate in the central zone, and lymphocytes predominate in the peripheral zone.

3. The so-called pure epithelioid tubercle consisting of a nodule in which the epithelioid cell predominates throughout except for a narrow periphery of lymphocytes.

The first and last types were frequently noted in the material examined. The key to tuberculoid tissue is the ratio between the epithelioid cell and the lymphocyte. Tissue which shows a reaction of mixed epithelioid and lymphocyte cells in which tubercles can not be demonstrated is considered tuberculoid in structure. A definite ratio is maintained—one epithelioid and one lymphocyte or two, three, four, or more epithelioid cells to one lymphocyte or one epithelioid cell to two, three, four, or more lymphocytes—with enough epithelioid cells in the focus of infiltration to be prominent. Giant cells may or may not be present in either group.

Besides the changes in reference to the epidermis, blood vessels, and appendages, the cases were revealed according to the

concepts as shown in Table I.

The cases are placed in four classes.

Class 1 (Agreement)

There were 119 cases in which the clinical diagnosis and the histologic interpretation were in agreement. In many the agreement was based on correlation with the clinical description.

Lupus vulgaris: 22 cases (all with tuberculous structure.)

Lupus miliaris disseminatus fac.: 8 cases (all

with—ous structure.)

T.b. cutis: 18 cases including 2 with mixed clinical lesions in colored patients. (Lupus miliaris des. et fac. keloid and t.b. cutis) and (miliaris lupus l.v. and l.e.)

T.b. ver. cutis: 4 cases including 2-ous; 2-oid.

Lupus pernio (possibly): 1 case—ous. Erythema induratum: 5 cases. 1—ous; 3—oid; 1 predominating lymphocytic.

Lichen scrofulosorum: 2 cases. Both—oid.
Sarcoid Boeck: 5 cases. 4—oid; 1 lymphocytic principally.

Darrier roussy 12 cases 4—out, 8—oid Papulo necroite tuberculide 15 cases 2—ous, 12—oid, 1 predominating lymphocytic

Granuloma annulare 1 case—oud
*Lichen nitidus 5 cases 1—ous, 4—oud
*Acne rarioloformis 4 cases 2—oud, 2 lympho
cytic

*Lupus erythematosus 15 cases
*Le pemphigoides (Senear Usher type)
cases

. Generally considered not of tubercular origin

Class 2 (Disagreement)

Seventy cases in which the clinical diagnosis was a type of tuberculosis tuberculid or borderline disease with or without an iterrative diagnosis and the histologic interpretation offered another diagnosis

Lupus vulgaris In six cases clinically diagnosed as lupus vulgaris the histologic interpretation resulted as follows two cases showed as infectious granuloma (an alternative clinical diagnosis of blustomycosis was offered in one) two cases showed as inflammatory process one case showed as syplulis one case showed as lichemification. In the latter case an alternative clinical diagnosis of lichen planus was offered

Lupus miliaris dessemmalus faciei. In three cases diagnosed chinically as lupus miliaris desseminatus faciei histologically showed as perifoliculitis In each case an alternative clinical diagnosis of lichen mitidus was offered

The vertices a cutis. In five cases diagnosed clinically as the verticutis the histologic in

terpretation resulted as follows two cases showed as intraepidermal epithelioma (One a so called Bowens the other a type seen in senile keratosis) one case showed as fibramiyoma one case showed as foreign body granuloma one case showed as inflammatory process

Tuberculosis cutts. In twelve cases diagnosed clinically as tuberculosis cutts the histologic meterpretation resulted as follows six cases showed as nonspecific granuloma or granulation tissue. In one crise an alternative clinical diagnosis of bhistomycosis was offered and in an other case an alternative clinical diagnosis of proderma was offered three cases showed as gumma. An alternative clinical diagnosis of actinomycosis was offered in one case one case showed as Ilymphoblastoma. An alternative clinical diagnosis of epithelioma was offered in this case one case showed as psoriasis one case showed as sporiasis one case showed as psoriasis one case showed as epithelioma (squamous celf)

Lichen scrofulosorum. In three cases diagnosed clinically as lichen scrofulosorum, one showed as an inflammatory process and two

showed as vesicular dermatitis

Lupus permo In two cases diagnosed clinically as lupus permo one was returned as erythem induration and the other as acanthoma. In the latter artefact was offered as an alternative clinical diagnosis.

Erythema induration In no instance was a case clinically diagnosed as erythema induration returned with a non confirmatory histologic

interpretation
Sarcoid In eighteen cases diagnosed clinically as sarcoid the histologic interpretation

resulted as follows: nine cases showed as inflammatory process. An alternative clinical diagnosis of Hansen's disease was offered once: three cases showed as lymphoblastoma. An alternative clinical diagnosis of fibrosarcoma was offered in one of these cases: two cases showed as lupus erythematosus. One showed as nevus and here an alternative clinical diagnosis of xanthoma was offered: one case showed as scleroderma (possibly): one case showed as endothelioma: one case showed as erythema (desseminated sarcoid was the clinical diagnosis).

Papulo necrotic tuberculid. In thirteen cases diagnosed clinically as papulo necrotic tuberculid the histologic interpretation resulted as follows: eight cases showed as inflammatory process. An alternative clinical diagnosis of lichen nitidus was offered in one case and of pityriasis lichenoides varioliformis in another: two cases showed as syphilis: two cases showed as fibroma; one case showed as molloscum con-

tagiosum.

Lupus erythematosus. In seven cases diagnosed clinically the histologic interpretation resulted as follows: two cases showed as vesicular dermatitis: two cases showed as sarcoid, one of Boeck type, the other of Darrier roussy type. Three cases showed as inflammatory process.

Granuloma annularc. In one case diagnosed clinically as granuloma annulare a histologic report of fixed erythema was returned.

Lichen nitidus. No cases in disagreement.

Class 3 (Revealed Microscopically)

There were nineteen cases in which the clinical diagnosis was other than a disease of the group but in which microscopic examination identified a disease of the group. They are given as follows with the clinical diagnosis and the histological report:

Epithelioma: 4 cases. 1 T.b. cutis; 2 Boeck's sarcoid; Lupis des. fac 1.

Hodgkin's Disease: 1 case. T.b. cutis. Hansen's Disease: 2 cases T.b. cutis and Darrier roussy. T.b. cutis (no question. Blood vessels at periphery dilated and enlarged). (Tubercles with necrosis and fibro tissue change.)

Syphilis tertiary: 2 cases Acne keloid: 1 case. Miliary lupus (later proven clin.)

Lichen planus: 3 cases. Lichen nitidus 1; Boeck's sarcoid 1-oid, can't place, 1.

Mycotic nodules (tape worm): 1 case. T.b. cutis (classical tubercles).

Lichenified eczema: 1 case. Lichen scrofolo-

sorum.

Keratosis: 1 case, Tuberculoid structure (can't place).

Granuloma inquinale: 1 case. T.b.c. vs. syphilis

leaning to t.b.

Acne vulgaris: 1 case. Tuberculoid. Pityriasis ruba pilaris: 1 case. Lichen nitidus.

A comparative summary of the cases in Class 1, 2, 3, is shown in Table II.

Comment: It is interesting to note that, in spite of the fact that lupus erythematosus does not present a consistent characteristic histologic picture, confirmation was obtained in a high percentage of cases. The histologic findings usually coincide with enough of the cardinal clinical signs to allow the agreement. That is hyperkeratosis, atrophy, pigmentation, erythema, telangicctasia are reflected in the microscopic picture. In addition a fair percentage show basophilic degeneration which is an aid to the histologist.

Class 4 (Unsatisfactory)

Thirty-two cases with clinical diagnoses were included in this group and with material considered unsatisfactory for histo-

logic interpretation or unreliable.

Of the reasons for failure the most common was the lack of depth of material. Also noted was material showing granulation tissue or fibrosis suggesting the fact that a better site could have been chosen for biopsy.

Included in the class were nine cases that histologically presented features of tuberculosis and syphilis impossible of definite

differentiation.

Conclusions

 Tuberculous or tuberculoid structure may be included or may be entirely lacking in histopathologic specimens of skin diseases in the group classified under tuberculosis.

2. Histopathologic studies of diseases in the group are valuable to the clinician, very often supporting the clinical diagnosis, frequently supporting an alternative clinical diagnosis and occasionally revealing unsuspected diagnoses.

Diseases of the group often imitate other dermatoses clinically and histologically. 136 East 64th Street

THE VALUE OF THE ERYTHROCYTE SEDIMENTATION RATE DETERMINATION IN PSYCHIATRIC CASES

Hugh S Gregory, M.D., Binghamton Pathologist Binghamton State Hospital

The phenomenon of erythrocyte sedimentation may be observed in some degree in all blood specimens to which some anticoagulative substance, such as potas sium oxalate or sodium citrate, has been added. The rate of cell sedimentation has been found to show acceleration, especially where there is clumping of the erythrocytes into large aggregations. Stoke's law reads, "The sedimentation velocity of the corpuscle, in a suspension of globular elements in fluid, is proportionate to the square of their radius"

A vast literature has accumulated concerning the clinical application of this test and many claims have been made as to its value, both as an aid in diagnosis and as a criterion of the progress of organic pathological states The diseases in which acceleration of sedimentation rate has been demonstrated are, generally speaking, those in which there is extensive inflammation, tissue cell destruction, or new growths As can be readily seen, these types of pathology include a large proportion of organic conditions There are several modifying factors which should be kept in mind A slightly higher rate is found in females than in males Diminished degrees of concentration of cells, as in the anemias, increase the rate 1 The longer the specimen of blood is kept before applying the test, the lower the rate is apt to be found?

Goldwin, of the Worcester State Hospital, reported normal rates in the functional psychoses except where marked mental deterioration or gross physical factors were present. He reported increased rates in semile psychoses, cerebral arteriosclerosis, neurosyphilis, mental deficiency, acute alcoholism psychoses with somatic disease, and in many cases of epilepsy and involution melancholia. Freeman, of the Worcester State Hospital reported normal findings in demential precox. Glaus reported normal rates in manic depressive insanity, psychopathia,

neurasthenia livsteria, and epilepsy. He found contradictory results in dementia precox, and increased rates in senile dementia, cerebral syphilis, and progres sive paralysis 5 Stephenson, of the Boston State Hospital, reported increased rates in infection, tissue damage, and pregnancy She also found the rate increased in many cases of mental defect who did not show the above pathology She did not find the rate increased because of mental deterioration 6 Opsahl reported increased rates in certain cases of dementia precox with accompanying physical disorders found that medicinal agents, such as barbital, trional, bromides and opium, did not influence the rate 7

The present study was prompted by the desire to utilize still another laboratory aid in detecting organic pathological states in psychiatric cases and the writer confesses to influence by the splendid writings of Osgood and Haskins of the University of Oregon Medical School, in which a modification of the Westergren technic is described 8 The practical suggestion by this group of workers that fourteen different tests may be applied to oxalated blood. including the erythrocyte sedimentation rate determination, seems a valuable one for mental hospitals. They advocate the use of oxalated blood for the following tests-hemoglobin estimation, red cell count, platelet count red cell volume color, volume and saturation indices, icterus index, Van den Bergh test, white and differential cell counts, peroxidase test, fragility test, and the sedimentation rate determination The writer feels that in many cases coming to mental hospitals there is an emotionally disturbing effect produced by repeated venipunctures, so that any plan which permits the perform ing of a great variety of laboratory procedures with a single sample of blood, not only serves to minimize this emotional factor with the patient but also proves to be a great saving of time and labor to the physician whose duty it is to collect the specimens. Also, although irrelevant to the subject of this paper, it might be added that the writer for the past three years has used the plasma from oxalated blood for both the complement fixation and Kahn tests for syphilis with excellent results and has routinely performed these tests together with sedimentation rate determinations, blood counts, blood chemical determinations, and so forth, with a single specimen of blood from newly admitted cases.

The technic of the sedimentation rate determination employed in this study is essentially that of Osgood and Haskins. The blood, collected in a tube containing two drops of twenty per cent potassium oxalate solution, is immediately agitated on being received at the laboratory to insure thorough mixing, and a Westergren tube is filled to the 200 mm. mark. tube is placed in a suitable rack to prevent the blood leaking out. These Westergren tubes are really pipettes of about 300 mm. length and 2 mm. bore and are graduated to 200 mm. from the tip. They are purchasable from any laboratory supply house as are also suitable racks to hold However, it is possible to insert the tip of such a tube in a hole bored onehalf the distance through a rubber stopper, the hole being made slightly smaller than the outside diameter of the tube. stopper is then inserted in a hole in a wooden block which is bored to hold such stoppers, and thus the tube is held in a vertical position and the conditions of the test easily complied with. The tube so filled, is allowed to stand for forty-five minutes, and the number of millimeters of sedimentation of the cell column is noted at the end of fifteen minutes and again at forty-five minutes. fifteen minute reading is subtracted from the total forty-five minute drop and the difference divided by two. The number of millimeters drop for the first fifteen minutes is compared with this quotient, and the greater figure of the two is called the "sedimentation rate." This figure rarely exceeds six millimeters in normal controls and is often found to be only one or two millimeters. While this technic differs somewhat from the methods employed by other workers, notably that of Linzenmeier, it is more easily applied to large numbers of specimens and does not require constant attention during the period of observation. An alarm clock aids the worker in performing the test by permitting him to attend to other duties in the intervals between readings.

The following observations with the blood of 1,102 psychotic cases are briefly reported to show our experience with this test at the Binghamton State Hospital during the past three years. While the number of cases studied seems to be large, it was found on separating them into their diagnostic groups according to psychosis, that some groups are too small to afford convincing results. These results are reported, however, without apologies as it seems possible to draw certain conclusions from them. this procedure has been continued longer, a much greater variety of disease conditions will have been encountered and a more comprehensive interpretation will then be possible.

To enumerate all the assigned causes for the increased rates found by this study would be impracticable, so only brief generalizations will be made. For ease of presentation some of the observations have been tabulated. (See accompanying tables.)

On studying the causes of the relatively few increased rates found in the so-called "functional" group of psychoses it was found, with an occasional unexplained exception, that all were due to intercurrent diseases such as dental infections, gingivitis, acne vulgaris, urinary tract infection, respiratory tract infection, new growths, and so forth. Several high rates seemed to be due to recent inoculations against small pox, typhoid, and diphtheria. Generally speaking, increased rates were more frequent in older people but only because of the more frequent occurrence of physical disorders. The acute excitements of the manic group, with the tendency to bruises, exhaustion, and dehydration, also seemed to predispose to higher

In the group of organic psychoses, the high rates seen in many senile and arteriosclerotic cases are explained by the frequent occurence of terminal cardio-renal, respiratory, and other diseases common to persons of advanced years. Occasional

393

cases, with extensive cerebral hemorrhage or softening, gave high readings. The increased per centum in the group of psychoses with somatic disease requires no comment

The findings in the group of cases of general paralysis proved something of a surprise for there were found relatively

Those cases in few extremely high rates which accelerated rates were found, showed no correlation with the degree of meningitis present, as shown by cerebrospinal fluid cell counts Some high rates were obviously due to intercurrent dis eases but the balance must be tentatively atttributed to tissue alterations due to the activity of the spirocheta pallida in nervous and other structures. As shown in one of the tabulations, sixty five of the ninetythree cases of parests were found on admission to have normal sedimentation An occasional case of acute lepto meningitis due to progenic organisms, showed high acceleration in contrast with the more chronic type of meningerl inflammation seen in general paralysis

By way of control, twenty one determinutions were made with blood specimens of supposedly normal non psychotic persons and all the results obtained were within normal limits

The comparative value of potassium oxalate and sodium citrate as anticoagulints was observed in a small series of duplicate tests, and the former seemed to give slightly more accelerated rates. There was however, very little difference

Conclusions

The erythrocyte sedimentation rate de termination, based on the study of blood specimens (oxalated) from 1102 newly admitted patients to the Binghamton State Hospital over a period of three years, seems to permit the following conclusions

1 It is not diagnostic of any particular

psychotic group

2 It is a valuable diagnostic and prognostic aid in evaluating organic path ology in all types of mental cases often revealing the presence of previously unsuspected disease and giving an indication for further physical diagnostic studies

3 Higher rates were obtained in the group of organic than in the group of functional psychoses because of the more frequent occurrence of inflammations, new growths, tissue degenerations, and so forth

4 The test is sensitive to acute respiratory infections including the common cold, and to immunization inoculations which must be ruled out in searching for underlying pathology.

- 5. Potassium oxalate is a satisfactory anticoagulant making it possible to apply the test with oxalated blood specimens sent to the laboratory for other types of examinations.
- 6. The technic is so simple as to make the test a boon to the private practitioner as well as to the hospital pathologist.

The appreciation of the writer is acknowledged to Dr. William C. Garvin, Superintendent of the Binghamton State Hospital, for his interest and encouragement in making this study possible and also to Dr. Clifford E. Howard, physician in charge of the reception hospital, for collecting the oxalated specimens of blood in this large series of cases and for furnishing the clinical findings in these cases which has enabled the drawing of deductions as to the value of this test.

AMERICAN COLLEGE OF SURGEONS SECTIONAL MEETING, MARCH 26-28, 1936

The Sectional Meeting of the American College of Surgeons at Buffalo is to be held March 26, 27, and 28, 1936. Headquarters will be at the Hotel Statler. The participating states will be New York and Pennsylvania, and the province of Ontario.

The program includes operative clinics in the Buffalo hospitals in general surgery, eye, ear, nose, and throat surgery, and the other surgical specialties; medical motion pictures; scientific sessions; and a hospital standardization program consisting of addresses, round table conferences, discussions, demonstrations, and visits to local hospitals. A Community Health Meeting will be held on the evening of March 27, to which the public is invited.

Fellows of the participating states and province and a group of visiting surgeons will furnish the program for the scientific sessions. Among the visiting surgeons who will be present to participate in the various

programs are:

Frank E. Adair, M.D., New York, Attending

Surgeon, Memorial Hospital. Frank H. Lahey, M.D., Boston, Surgeon, New England Deaconess and New England Baptist Hospitals.

Robert B. Greenough, M.D., Boston, Consulting Surgeon, Massachusetts General and Collis P. Huntington Memorial Hospitals.
Frederic W. Bancroft, M.D., New York

City, Associate Professor of Clinical Surgery, Columbia University College of Physicians and Surgeons.

Perry G. Goldsmith, M.D., Toronto, Professor of Oto-Laryngology, University of Toronto Faculty of Medicine.

William J. Engel, M.D., Cleveland, Surgeon, Cleveland Clinic Hospital. Charles L. Scudder, M.D., Boston, Consulting Surgeon, Massachusetts General Hospital.

Grover C. Penberthy, M.D., Detroit, Associate Professor of Surgery, Wayne University College of Medicine.

Malcolm T. MacEachern, M.D., Chicago, Director, American College of Associate Surgeons.

Bowman C. Crowell, M.D., Chicago, Associate Director, American College of Surgeons. Jolly, Houston, Superintendent, Robert Memorial Hospital.

EXAMINATION FOR UNITED STATES PUBLIC HEALTH SERVICE

An examination for entrance into the Regular Corps of the United States Public Health Service in the grade of Assistant Surgeon (medical only) is to be held April 13. Applicants must not have passed their thirty-second birthday. They must be graduates of a reputable medical college and have completed at least one year of internship since graduation, or its equivalent. The compensation is \$3,158 per annum with dependents and \$2,699 without dependents. Boards will be appointed in various cities so as to cause as little travel as possible, which, if necessary, must be made at the candidate's own expense. The examination will consume about one week. Persons desiring to take this examination should make request to the Surgeon General, U. S. Public Health Service, Washington, D. C., for blanks and information.

A tropical fever spread by mosquitos that are able to survive bitter Siberian winters is among the by-products of studies now being made of eternally frozen soil by Soviet scientists.

THE TREATMENT OF GASTRODUODENAL ULCERS AS AN OFFICE PROCEDURE

ANTHONY BASSIER, M D, New York City

The contact man in the ulcei case is most commonly the general practitioner Because his role is large he may not be the most capable in instances of ulcer that tax even the skill of the specialist Each has his place in this field Deducted from the study of any condition in medicine the specialist should pass on that of the worthwhile in routine and particular satisfaction to general practitioners of medicine This is one of the responsibilities of specialists not observed to the extent that it should be There have been cases of ulcer which the general practitioner has handled as well as a specialist. But there have been many in which this was not so, and this even in the uncomplicated case

Peptic ulcer is now supposed to be a systemic disease. This is only an assumption predicated on a diverse lot of clinical findings met in miny cases. The play of constitutional emotional, and local factors influences results of treatment. Thus these patients should be examined thoroughly for any constitutional condition that lowers the resistance of mucous membranes or restricts reparative processes. Quite obviously the treatment of ulcer comprises also the treatment of other conditions of the body in addition and the results both medical

having infected tonsils teeth sinuses and other focal infections controlled, and by paying attention to bacterial intestinal states without using ulcer diets, alkalies etc.

and surgical are considerably conditioned

by these Not a few ulcers are cured by

As a rule the lesion occurs in regions which are in contact with hydrochloric acid. There has never been an ulcer case with symptoms that did not have hydrochloric acid in the stomach and it is agreed that its control or neutralization is beneficial. It can be taken as definite that if an ulcer is present and there is no hydrochloric acid, there are no symptoms from the ulcer. Therefore the use of alkalios is essential but not to the extent of alkaliosis (even of moderate degrees).

which is especially liable to happen in the Sippy method because in addition to the excess alkalies, it is a low silt type of diet. The establishment of distinct degrees of alkalosis is almost as harmful to a cure as to use no alkalies at all

A study of cure statistics from bed handling of different observers shows them mentioned from thirty-five to sixty Matching one hundred ambulatory clinic cases of ulcer with one hundred private cases handled in bed on the basis of results from the immediate handling and follow up for twelve months. shows practically the same results is interesting in that the clinic cases generally were poor, ignorant types of people, difficult to control, and limited in home environments, while the private cases were a much more superior lot The final result of this experience is that every case of noncomplicated ulcer in the author's private practice today is handled as an office procedure In 492 private cases since that time there have been but fortyone in which operations were advised This does not mean that ninety-two percent of them are cured of their ulcers, but it does mean that in two year observations twenty six percent of them are free from symptoms, forty-two percent have very few and insignificant conditions while twenty-four percent showed moderate improvements, leaving but eight percent judged as unimproved

Comparing this with the best statistics on hand of those who hospitalize all cases of ulcer for approximately four weeks it matches up very satisfactorily and obviates the atavistically held opinion that bed treatment is essential

There is only a small percentage of ulcer cases in which bed treatment is wisest. These comprise those in whom study is a requisite, frank hemorrhage cases—where more or less continued bleeding is present—those that are truly surgical at the time of seeing them first, the perforated, the organic obstruction of the pylorus, the occasional case where for economic or domestic reasons control of

diet or a rest in bed seems indicated, and the case, especially gastric, where the x-ray defect remains constant.

One must not forget in this whole affair that ulcer is essentially a chronic disease, and that putting instances of chronic disease to bed is not accepted as a universal essential of therapy. Another thing to be remembered is that ulcer is characteristically a remissive disorder. Even the bed case must return to civil life, and that the main essential in treating this disorder is the education of the individual who is valueless unless he can carry out his instructions in connection with daily life. Also, there is the convenience of making x-ray studies which private patients are willing to engage in if they can continue their work during the time the observations are made. relapses that occur from fatigue, emotion, and infection affect the individual when up and around, and it is illogical to put the patient to bed for four weeks each time the relapses occur. Exhausting work is the cause of relapse in one-fourth, emotional excitement, worry, and grief in one-fifth, and infections in one-seventh. Certainly colds and grip and metabolic affairs are factors of moment. reliably reported that among the 25,000 agents in the Metropolitan Life Insurance Company there are thirty-five cases of ulcer in every thousand. These are all hard-working people who are on their feet a great deal. For economic reasons they cannot be put to bed; and, since our hospital experience shows only a very occasional one that perforates or has frank hemorrhage, it is questionable that treatment is necessary.

Ulcer is rarely a fatal disease, and death from it will be less common in the future. Watched over a course of years, only about one-half of the ulcer cases that die expire from ulcer; and of these about one-fourth die from hemorrhage, onethird from perforation, and a little less than one-half from obstructions and complications. Viewing surgery from a medical standpoint it is not without interest to observe that, while surgery gives a higher percentage of continuous relief, surgical failures are more than double that of medical failures, and the proportion of satisfactory results is distinctly In this, of course, one must lower.

appreciate that the surgeons operate upon the more serious and intractable cases such as perforation, obstruction, etc. Surgery, however, appears just as unable to alter the course of peptic ulcer as medical treatment, a matter that probably will be improved if attention to general health and after care were insisted upon by surgeons to the extent that they are being carried out by the medical men. This probably explains the better results in the average case from medical handling than surgical.

The first item in the handling of the uncomplicated ulcer case is the diet which should be balanced, consisting of fluid or finely comminuted foods, bland and non-irritating, with restrictions on alcohol, condiments, carbonated fluids, and the use of tobacco. The following plans are preferred in the ambulatory handling:

Diet for First Month

This diet is a temporary one and is to be continued until a change is made. The plan is not to partake of any solid foods whatsoever and to take the foods that are suggested at regular intervals of three or four hours during the day, attention being paid that a strict regularity is preserved and that the foods are divided rather evenly in quantity for each time.

A glass of plain fresh milk and perhaps a few crackers should always be taken before retiring, and an extra glass of milk during the night if there is distress in the stomach.

The diet consists essentially of only four foods, namely, eggs, fresh milk and cream, well-cooked cereals, bread and crackers; nothing else in the food or fluid line (except plain water) should be taken. Butter is allowed.

The eggs may be eaten raw or cooked in any form, or may be taken in the milk. The milk may be warmed if desired, but should not be taken too hot or too cold. The "ten minute" modern breakfast foods or any forms of oatmeal should not be eaten, the old-fashioned forms of ground corn, farina, rice, tapioca, or sago, well-cooked, being the best. The bread should not be too fresh (one day old); any of the sweetened or unsweetened crackers can be used and all forms of simple cake, providing there are no nuts, raisins, seeds or preserved fruits in it.

The total amount of food in one day should be—four eggs, one quart (4 tumblerfuls) of milk, one-quarter of a pound of fresh unsalted butter, or one-eighth of a pound of butter and an extra quart of milk,

two rolls or four medium thick slices of white bread, one-quarter of a pound of baker's cake or crackers, one-half pint of fresh cream, and one-quarter of a pound of cereal (weighed dry). This represents 3700 calories, and in instances, modification of quantity is permitted.

Diet for Second Month

Now the 8, 12, 4 and 8 o'clock meals are diversified with the following selections, plain milk (not fermented) being taken midway between the meals and alkaline powders, one hour after each feeding:

Purees or creamed soups (barley, rice, peas,

beans, celery). Gruels (flour, cracker, barley, Indian meal, farina).

Plain crackers, baker's cake, pound cake, toast, rolls, jellies, rice, tapioca.

Ground or mashed vegetables,

Puddings, rice, tapioca, bread, cracker.

Custards, vanilla and chocolate, blanc mange, whips and souffles.

Gelatins-flavored with any fruit or berry juice. Plain ice cream-not too cold.

Malt-milk cocoa, cocoa, chocolate, Diet for Third to Sixth Month

The general plan of this diet is to take three moderate sized meals at regular intervals during the day, and to take supplemental meals of milk, re-enforced with cream, cocoa and crackers between meals and before retiring. Altogether, foods should be taken at least five times during the day.

All of the solid foods should be tender, cut very fine on the plate, and thoroughly

masticated before swallowing.

The foods permitted for the main meals are:

Beef, lamb, and chicken, roasted or broiled and taken only once a day. Fish, any kind and in any form excepting

fried, taken once a day, Eggs in any form, other than fried, and taken

once a day.

Cereals (with the exception of oatmeal and shredded wheat biscuits) well-cooked and taken with cream in the morning.

Vegetables—any that are well-cooked and mashed with the exception of green vegetables. May have the tubers, such as baked or wellmashed white potatoes, squash, parsnips, and turnips.

Desserts-any made of milk, cereals, and jellies.

Do not take fruits, berries or nuts,

Butter, cream, milk and cereals, and eggs still remain the main foods of the daily diet, If the symptoms become marked again these should be the main articles of the diet for a while, when the more general plan may be followed.

The best drink at the meals is Vichy Celestins or any alkaline water (Kalak, Saratoga). Remove all the fats from foods.

Diet After Sixth Month

At the end of six months a normal diet is employed.

Foods that should not be partaken are:

One or two minute cooked breakfast foods. The rough vegetables such as cabbage, sprouts, cauliflower, artichokes, asparagus, beets, celery, corn, cucumbers, kohl rabi, onions, and tomatoes.

Foods which contain pits, seeds or skins or

nuts.

 \mathbf{R}

Canned or smoked meats or fish. Lobster, crab or shrimp.

Cheese of any kind except Philadelphia or Neufchatel. Too much pastries, especially those cooked in

molten fat like doughnuts, fritters, etc.

Foods that are too sweet, such as jams, etc. Coffee, strong tea, alcoholic and malt beverages are not allowed.

Do not eat fat from meats and keep on a non-fat plan. Smoking is not good for these patients.

Instruct patients to report at once if any stomach symptoms arise.

Rest each day in the supine position is increased from the usual eight in twenty-four to nine, ten, eleven, and This should be insisted twelve hours. upon, the first month being twelve hours, the second eleven, and so on down to eight hours a day. No extra exercises are allowed, simple walking is sufficient for the first three months of treatment, all activities being reduced to a minimum. Either one of the accompanying alkaline

formulas can be used and in those not containing belladonna or atropine, an atropine tablet of 1/100 gr. is given at bedtime to control the night gastric secretion. Effort is made by changing the formula, kinds and doses of alkalies. to render the urine amphoteric, the patient using litmus paper to observe this. If the pain does not subside in a week's time, subcutaneous injections of aolan may be used since often a foreign proteid product There is no like this may be helpful. objection to Synodol, Larostidin and like products, but they should not be depended upon alone. The bowels may be regulated by magnesium oxide. Iron injections are employed in anemia and the patient should be warned against taking cold and becoming excited by business and family troubles, movies, shows, etc.

X-rays should be taken each month, the course watched especially when there is slow bleeding or a question as to the type of pyloric obstruction that is present. These films should be matched as to defects, peristaltic phenomena, etc.

Treatment should not stop with the clearance of symptoms. In the instances of relapse one should not lose faith and impatiently to more There are quite a number of measures. these patients who have gone through two or three courses of medical handling for remissions and then become substantially It is impossible to know what will happen in an individual instance of uncomplicated ulcer. The more one sees of ulcer cases in results, the less definite one can be. If, however, bleeding continues, the pyloric obstruction has not abated (making allowance for the slow emptying stomach pylorus nonobstructed), and the defect continuing or enhancing and the complaint and patient's general condition is not markedly improved, operation should be considered, but it should not be advised on relapses alone unless the complications mentioned are present when the case is first seen or has become definite during the observations.

About one-quarter of all ulcer cases have a drip bleeding at least at some time.

These when seen first should be treated medically. In the instance of frank and alarming hemorrhage, the treatment is medical also, usually with the addition of enforced complete physical rest and bed treatment for a while with frank doses of morphine, ice water lavage of the stomach, and dram doses of adrenalin chloride solution. Hemorrhage from an ulcer, even a frank one, has only one percent danger of death. Surgical intervention does not control hemorrhages at the time or prevent future bleedings any better than does medical treatment. However, these cases should be viewed as surgical possibilities during the medical handling and must be closely watched with this in view. Excepting in perforations (which require prompt surgical handling), one should hesitate about operations when the stomach secretion is high. It is difficult to reason why this is more dangerous. A half played-out stomach stands operation best, and generally the patient recovers from the operation with a good result.

Finally, the guarding against alkalosis by the litmus paper method is a satisfactory clinical guide and obviates frequent blood chemistries. Small doses of mercury bichloride and trioxide of arsenic thrice daily by mouth does something in healing ulcers. The plus Wassermann or Kalın case needs specific additions, preferably administered hypodermically. The Sippy method for bed handling is as satisfactory as any. However, the Lenhartz or others are quite as satisfactory and often less troublesome to carry out. All of these are not practical in dieting when out of bed. To them, although, the evening dose of atropine is a worthwhile addition.

Summary

A method for the ambulatory treatment of ulcer is offered, one that has proven of value to the exclusion of bed treatment.

A dietetic plan for months of handling

is presented.

A simple method to control alkalosis is given. 784 Park Avenue

A New York doctor, treating an old lady for rheumatism, was flexing the fingers of her right hand. "That hurts, doctor," she

said, "what do you do that for?" "I want to keep your fingers limber," he replied, "so that you can sign checks!"

GALL-BLADDER DISEASE

MALCOLM H V CAMERON, FACS, FRCSC, Toronto, Canada

Experience with disordered biliary function differs with type of practice Both the general practitioner and internist know most about its earliest manifestations and are best qualified to evaluate the results of treatment. The surgeon meets with it after signs have been added to symptoms and is often asked to rescue a patient after serious damage has been sustained. The sufferer from biliary disease is fortunate when he finds an internist who realizes the necessity for surgical interference when it arises, and a surgeon who belongs to the highest order of his craft is an internist who can operate

The earliest complaint of the patient with this disorder is dispepsia and there are many studies to prove the assertion that dyspepsia caused by an organic lesion originates in half the number of cases in

the gall-bladder

The oft-quoted study of Alvarez reveals that of 500 patients who complained of indigestion, 175 of them had organic disease and of these seventy seven were diagnosed as cholecy strits or cholelithiasis. A large group studied by Blackford and Dwyer showed 1,650 patients with organic dyspepsias. The causes were listed as to percentage. Gastric ulcer, 4, gastric cancer, 8, reflex appendix, 16, duodenal ulcer, 24, cholecystitis, 48

When a patient asks for relief from disturbed digestion we carefully go over the listory Age is important for though there are many instances of cholelithiasis in the very young and many more in the very old, the fifth and sixth decades will be noted most frequently. Sex is important because women outnumber men by four to one in all large tables of statistics in this disease. Occupation may be of less importance. The duration of the symptoms must be ascertained.

A short history of dyspepsia in a patient past middle life is much more indicative of gastric cancer than any other lesion. A long history with symptoms noted day by day suggest gall bladder disease if visceroptosis is ruled out.

Should there be added intermittent attacks of colic, calculi in the gall-bladder may be assumed to be present

The individual symptoms are then

taken up one by one

Pain This amounts only to discomfort excepting when a stone passes or attempts to pass the cystic duct. The pain is then very severe and is characterized by regular accessions and remissions. At the onset the distress becomes more and more severe with each accession until it seems to the patient to become unremitting Close observation shows that there are remissions and that a true colic exists Graphically the spasms resemble the temperature chart of lobar pneumonia rather than that of septicemia As time goes on the daily discomfort increases and the range of radiation widens The right subscapular ache is characteristic of a well established inflammation of the gall bladder associated with Should the pain be of extreme severity and if accompanied by pyrexia, acute cholecystitis is to be borne in mind, and if by chill and fever the inflammation may be assumed to have extended into the liver radicles

Vomiting may or may not occur It gives immediate relief in gastric ulcer, partial relief in cholecystitis, and none in gastric

cancer

Appetite in gall-bladder disease is usually good but may be impaired by flatulence Food selection is practiced on the principle of trial and error Seldom is one of these patients seen who can tolerate a raw apple Other foods may sometimes be digested in comfort though severe upset may follow their ingestion on another occasion. If the patient be a man he should have a wife who is able to secure any food material-vege table or animal-to order or attend to its preparation, who is able to answer all his objections out of a knowledge of physiology and biochemistry, and who is a saint and the apotheosis of patience as well She would understand the statement of the late C S McVicar who said that if you are with a man when his attack comes on he will hurry to the Litchen for some baking sody if he has duodenal ulcer, but he will stand and argue with you if he has a gall

Loss of weight is not a symptom as it is in cancer of the stomach or pancreas, but sudden and marked loss follows impaction of a stone in the common duct.

Constipation of the spastic type is usual

and may be of marked severity.

Mental depression may be quite marked and change of disposition increases as the disease progresses.

The signs may not be obvious. Tenderness complained of when the gall-bladder is palpated indicates that the disease is acute or that a chronic process is well-advanced. Evanescent jaundice due to congestion in the mucosa of the common duct may follow an attack of colic. Obstructive jaundice should mean stone in the common duct until proven by operation to have been caused by carcinoma or other internal cause.

Cholecystography should be used as a means of estimating function in the gall-bladder. A functionless gall-bladder harboring stones is a menace to the body and should undoubtedly be removed.

The author does not advocate surgical interference in acute cholecystitis. Mc-Kinty of Montreal and some others draw an analogy between acute cholecystitis and acute appendicitis. Their views are not widely accepted. The author was taught a severe lesson once by removing a gall-bladder four weeks after an acute attack; in thirty-six hours the patient was dead from septicemia, the culture of the blood showing a heavy growth of streptococcus. Months rather than weeks should be allowed for the inflammation to subside.

There is one condition in which acute cholecystitis should be treated as an emergency. In 1925 the author reported seven cases of acute gangrenous cholecystitis, and in the next five years eight additional cases came to his service in St. Michael's Hospital. The first case was diagnosed as perforation of a duodenal ulcer. The case was operated six hours after the onset and, as the author packed about the colon, the unsupported gallbladder separated from the liver and hung by the cystic duct. A clamp was applied, which cut through the pedicle freeing the gall-bladder. A ligature was applied and the cholecystectomy was completed. Another one came to operation on the fourth day and the same thing happened except that when the clamp was closed it came off with the gall-bladder. The

vessel was secured but this patient died. The first one recovered.

In the other cases the gall-bladder was drained following removal of stones and in three of them a cholecystectomy was done some months later. (The author having read everything available on this condition is forced to believe he has had a unique experience. Many surgeons with wider experience have never encountered a similar case. Torsion of the gall-bladder he has never seen.)

In all of these cases the differential diagnosis was most difficult. In all of them the onset was sudden, the abdomen exhibited true rigidity, there was fever and a high leukocytosis. These are mentioned only as a warning that an acute cholecystitis may not run true to form and that the established rule of expectant treatment may in the rare instance lead to catastrophe.

In chronic cholecystitis there is an optimum time for interference. As the gall-bladder gradually ceases to function, there develops a compensation in the liver and ducts. The intestine becomes accustomed to a lessened inflow of concentrated bile and physiological adjustment follows. Removal of the gall-bladder is then the breaking of a vicious circle of infection from the gall-bladder walls to the liver, from the liver to the bile, and back again to the gall-bladder. The detoxicating function of the liver thus becomes impaired and all metabolic processes are depressed.

There has been much speculation upon the source of the infection in cholecystitis. Following the report of Rosenow's work and, later, the thesis of Wilkie, the author began the practice of sending in a sterile container to the laboratory for bacteriological study as well as section every gall-bladder removed. As frequently as possible a small section of liver tissue was included. A colleague, Dr. Michael's Magner, pathologist to St. Hospital, made cultures from the content, from the mucosa, and from the walls of the gall-bladder after the mucosa had been carefully removed. He found "typical" streptococcus in twenty-five per cent of the chronically inflamed specimens submitted. In every case in which liver tissue was examined with the excised gallbladder hepatitis was found along with the chronic cholecystitis.

Injections of cultures so obtained when injected into the lumen of the gall-bladder or portal vein of rabbits produced chronic cholecystitis in fifty per cent of cases. Injections under the serosa of gall-bladder in rabbits produced chronic inflammation in every case. These observations do not clear up the problem of the source of infection but they do seem to indicate that the digestive tract is more generally the source than are more distant foci such as teeth or tonsils. Whether hepatitis precedes or follows cholecystitis is still debatable.

The formation of calculi is a usual event in the course of chronic cholecystitis. They form in the intrahepatic ducts in rare instances and frequently in the extrahepatic ducts in cases of stricture following cholecystectomy. Gallstones seem to exist in a number of people who do not present the symptoms of gall-bladder disease. Postmortem statistics covering many thousands of autopsies have established this fact beyond peradventure. Thus although infection is a cause of the formation of biliary calculi there must be other factors which act with or without inflammation in their formation. These factors include disturbance in cholesterol metabolism, pregnancy, lack of vitamin A in the diet and, according to Dr. George Draper of New York City, a definite hereditary predisposition in people of certain skeletal

Gallstones may pass through the cystic and common ducts. The author is informed that Dr. Hugh Auchincloss is an enthusiastic hunter after such trophies and that he is frequently rewarded for his unpleasant search, vicariously conducted by his house surgeon, by the finding of a calculus after a patient has suffered a bout of biliary colic. The author knows of one old lady who had a severe attack in her forties with one recurrence thirty years later. She is now eighty-three and

has never had dyspepsia.

Cholecystectomy is the operation of choice with certain exceptions. Cholecystostomy is not to be disdained. In a fulminating inflammation it is, presumably, the only thing to do, and in obstruction of the common duct, choledochostomy and the removal of stones from the gall-bladder may be all that can safely be done. Should stricture follow drainage of the

common duct, an intact gall-bladder may be very useful as a means of diverting bile into the stomach or duodenum.

Obstruction of the common whether partial or complete calls imperatively for surgical intervention unless one can positively ascribe the symptoms to an allergic cause. An experience with this extremely rare condition has been reported by Graham in his book. Should the obstruction be partial one may choose a favorable opportunity to operate. These obstructions are usually due to calculi which may lie anywhere in the length of the duct. They may be due to external pressure from neoplasms in the pancreas or to carcinoma of the bile ducts. The latter condition is less frequent than is carcinoma of the gall-bladder, but it does occur in a small proportion of cases. The author's two cases were encountered in a month: a colleague in Toronto found two

in one week during September of 1934. Every patient with common duct obstruction should be offered the benefit of operation. Should carcinoma be found the bile may be carried past the obstruction by an anastomosis of the gall-bladder with stomach or duodenum or by an end to side anastomosis of the severed common duct with the duodenum. In case the obstruction be from stone, as it commonly is, the clearing of the duct is a veritable

resurrection to the patient.

After removal of a stone from the common duct, prolonged drainage is required. Observation of the collected bile from day to day would bring the realization that a change appears from four to six weeks after the operation. The bile is at first heavy and mucoid. The drain provides relief of pressure and the hepatitis slowly subsides. The bile becomes more limpid and diffuses instantly when poured into water. Only after this change is definitely observed is it safe to discontinue drainage.

The T tube of Deaver has many advantages. By its use bile may be fed to the patient by the simple expedient of snapping an elastic band about the doubled end of the external drain. This should be done for an hour after every feeding. Lord Moynilan suggests that drainage by a catheter serves well and that patients do not suffer much from absence of bile in the bowel. The author most respect-

fully but very firmly refuses to agree. The liver is essential to life and bile is essential to effective assimilation of food. The object of the drain is to decompress the liver and so hasten resolution of the inflammation in its ducts consequent upon the obstruction.

By way of describing a simple method of management of drainage in an ambulatory patient, it can be said that it works equally well in the recumbent position and gives the patient more freedom than is possible with an attached tube leading to a receptacle outside the bed. An ordinary four-ounce dispensing bottle is provided with a feeding nipple instead of a stopper. The vent in the nipple allows equalization of atmospheric pressure at the same time preventing spilling in case the bottle should be overturned. The external branch of the T tube is passed through a small hole cut in the side of the nipple below the vent forming an airtight connection. The free end reaches down into the bottle. A sling made of adhesive plaster is used to fasten the bottle to binder or to a bandage about the neck of the patient if up and about.

The after-care of patients who have been subjected to cholecystectomy or choledochostomy may, in many instances, be a problem of considerable difficulty. Full restoration of function is a happy result devoutly hoped-for but rarely attained. Liver and pancreas have suffered in the long continued chronic inflammation and postoperative scarring has resulted in some degree of fixation of the duodenum. A new set of symptoms may develop which suggest duodenal ulcer. Reflex pylorospasm may occur and certain food intolerance become established. In a proportion of cases this intolerance is quantitative rather than qualitative. To forestall such events as these a regimen is prescribed copied from Van der Hoof in his article on duodenal ulcer. Six feedings in twenty-four hours with avoidance of cooked fats, raw fruits, condiments and meat extractives, and a minimal indulgence in the social poisons constitute the main features of this plan of management. By it, appetite is satisfied with a small intake at the regular meal times. The between meals and bedtime feeding is simply provided in a glassful of milk taken plain or flavored to taste.

In summary, experience in handling dyspeptic cases has shown that the removal of the chief cause of a patient's disability will always relieve him but may not be sufficient to effect a perfect cure.

SIX IN FAMILY OF SEVEN CONTRACT PNEUMONIA

Six cases of pneumonia which occurred within a period of one week in a family of seven who were living in close, overcrowded quarters were reported by V. A. VanVolkenburgh, M.D., in charge of the Tompkins county health district.

In five members of the family, a diagnosis of lobar pneumonia was made and in one, a child of two years, a diagnosis of broncho-pneumonia. The eldest of the family, the father, was the last to become ill.

According to Doctor VanVolkenburgh, the father was seen by the physician on the day of onset. Sputum was obtained from him and found to be Type I. Forty c.c. of state concentrated Type I anti-serum were administered promptly by the physician, followed twelve hours later by an additional 40 c.c. The results were excellent in that the patient's temperature dropped following serum treatment and was not observed to rise over 100 degrees thereafter. Toxemia was absent. The patient desired to return to work on the third day. Serum sickness

did not develop and there were no sequelae. The case was treated in the home. These results are typical of what may be expected when serum is administered early and in adequate amounts.

The mother, who did not receive serum, is reported as having developed empyema. The three children with lobar pneumonia and the smallest child are making satisfactory convalescence. The older children are, of course, in the age group in which favorable results might be anticipated.

In this group of cases, at least, the infectiousness of the organism was recognized by friends and neighbors, who would not enter the house. Because of this, it was difficult to obtain help in caring for the children when the father and mother became ill.

Doctor VanVolkenburgh reports that the physician in charge as well as his colleagues in the community are enthusiastic over the effect of scrum in the case of the father.

SCARLET FEVER IMMUNITY

Production and Maintenance

A Study of Comparative Values of Raw and Modified Streptococcal Toxins

ROGER JAMES REID, M D, Thiells

I rom the Department of Mental Hygiene of the State of New Yorl, Letchworth Village

The primary object of this study was to ascertain the possibility of modifying the toxic action (as shown by its skin-reddening powers) of streptococcal scarlatinae toxins, without destroying its ability to produce ininumity to scarlet fever (as indicated by inducing negative skin tests in previously susceptible individuals)

The occurrence of a number of mild cases of scarlet fever in Letchworth Villinge, a New York State institution under the Department of Mental Hygiene, necessitated the skin testing of its entire population for susceptibility to the disease. The Dick test was carried out in the accepted manner! of using one skin test dose (1 std) of streptococcus scarla timae toxin,* i.e., the amount sufficient to produce an erythematous area ten millimeters or more in its longest diameter, twenty four hours after being injected intracutaneously into the forearm of a susceptible person.

Around two hundred of three thousand inmates tested reacted positively and of these, less than a hundred and fifty were available for the complete study. These were divided into three groups (I, II, and III) as nearly comparable as regards age range as circumstances would permit. The immunizing injections were given at weekly intervals to all except ten patients in one group, whom for purposes of this study, fortnightly intervals were used.

The raw toxin of streptococcus scarla tinae was prepared and diluted as required by the standards of the Scarlet Fever Committee, the original strength bong forty thousand skin test doses per cubic centimeter (40,000 std/cc) Some of this raw toxin was oxygenated and the resultant material hereinafter will be referred to as Modified Toxin H 12, a second raw toxin having two hundred thousand skin test doses per cubic centi-

meter (200,000 std/cc) was treated likewise and will be referred to as Modified Town H 11

Other workers have prepared to ods by various methods as Zellinka and Kurrtt,² Veldee,³ and Zoeller using formaldehyde as the modifying agent Veldee and some others have used potassium alum for this purpose. The Dicks' however, do not agree that the toxin of streptococcus scarlatinae can be converted into a toxoid.

To determine the amount of unchanged raw to an remaining in the oxygenated insternls, a number of skin tests were conducted Small quantities of the respective oxygenated to an expective oxygenation on expecting the standard oxygenation of the standard oxygenation of the standard oxygenation oxyge

From these figures it is seen that onetenth cubic centimeter of the one in five hundred dilutions of each of the modified toxins gives a skin reaction of comparable size but less intense than the standard Dick test of one skin test dose Therefore, each cubic centimeter of the oxygenited material does not contain more than five thousand skin test doses (5,000 std) of raw or unchanged toxin

The immunizing injections were given to three groups according to Table II

A few reactions developed from the injections, the most severe ones being

1 In group I after the fourth dose of raw toxin (27000 std) three patients developed typical scarlet fever rashes

2 In group II, each of two subjects developed rather severe local reactions at the sites of injections of the first two doses of Modified Toxin H 12

3 In group III after each of the first and second doses of Modified Toxin H 11 four children run temperatures around 100°F for

^{*} All the materials for testing and immunizing were supplied by a well known manufacturer

twenty-four to thirty-six hours; two of these had an associated emesis of a mild type. Curiously enough only one out of these four sub-sequently became a negative reactor. A fifth individual developed a severe local reaction at the sites of each of the first two doses.

Two weeks after the last dose and again after a six-month interval the available cases of all groups were retested for positive reactors. Both times instead of the usual one skin test dose (1 s.t.d.) being used, a dilution of streptococcal

scarlatinae toxin was prepared in which

one-tenth cubic centimeter contained two skin test doses (2 s.t.d.). Also, instead of the usual ten millimeter reading, all readings of five millimeters or more in the longest diameter were considered as positive. Doubtful cases were retested and where still doubtful were recorded as positive.

It will be appreciated that while such criteria are more strict than the accepted standards, their use permits the presentation of results based upon definitely negative readings. (Table III.)

Two weeks after the last injections.

These findings are in keeping with the known facts that raw toxin is the most efficient agent for inducing negative reactions in susceptible persons. They indicate that the modified toxin retrins an immunizing power to a lesser but not incomparable degree. Also, that very concentrated amounts given over a shorter period than the raw toxin will produce a high percentage of immunes.

After a six-month interval under these stringent criteria, a considerable reversal of readings (Table IV) is shown by the skin tests at that period. The greatest drop occurs in those receiving the raw toxin while the group given the modified toxins show much less reduction. The changes in percentage, however, do not accurately represent the facts as may be shown by a study of the individual reversals of readings.

The findings as revealed in Table V

make it apparent that in any group of individuals, after a period of time there will be a considerable percentage of reversals of readings, so that one cannot predict which individuals will remain immunized or which ones will lose immunity

As the age-modence for scarlet fever hes between the fifth and fifteenth years, the readings of individuals in this group were compared to those of persons over fifteen years of age (Table VI)

Both age-groups show a similarity in number of negative reactors and of re-

versals after a six-month interval

In an experimental attempt to ascertain the effects of longer intervals between injections and, of using larger amounts of modified toxin, ten individuals in group III were given fortnightly doses as indicated in the schedule of injections (Table II) and compared with those

given at weekly intervals. Comparisons are revealed in Table VII.

Of the group receiving fortnightly doses, one individual who was positive after the first two weeks gave a negative reaction after six months, but on the other hand, two negatives became positive. In the group receiving weekly doses, six positives became negative, while eight negatives became positive in six months. From which it would appear that increase of dosage and of interval between injections does not appreciably influence the production or maintenance of immunity by means of the modified toxins.

Conclusions

- 1. Evidence is presented that the raw toxin of streptococcus scarlatinae can be modified by oxygenation, and still retain its immune-producing powers.
- 2. The raw toxin of streptococcus scarlatinae produces the greater number of immunes upon initial retest, but the percentage undergoes a sharp decrease over a six-month period.

- 3. Modified toxins can be given in greater concentrations over a shorter period than raw toxin and produce a comparable percentage of immunes. The percentage decrease over a six-month period is much less than with the raw toxin, and a greater number of non-immunes upon initial retest will develop immunity over a six-month interval, when compared with susceptible persons receiving raw toxin.
- 4. Raw toxin produces some general reactions but few local ones, while modified toxins cause some severe local and general reactions.
- 5. Age does not appear to be a significant factor in the production nor retention of scarlet fever immunity in respect to which there is considerable unpredictable individual variation.

HOW CARS "GO OUT OF CONTROL"

There is a type of automobile accident in which the explanation commonly offered is that "the car went out of control." In many cases, however, according to Dr. Yandell Henderson, Professor of Applied Physiology at Yale, writing in Science, subsequent examination demonstrates that the steering gear, motor and brakes were in good order. It is hence really the motorist who "goes out of control" and the explanation for his action lies in an instinctive reflex, which submerges the conditioned reflex built up by driving a car. The reflex concerned is the "self-righting reflex," which is excited by any sudden disturbance of equilibrium, As we read in an abstract of his article by the A.M.A. Journal, Dr. Henderson explains that it is a complex reaction in which the head, body, arms and legs are all involved.

When it occurs in the driver of a car, the impulse that dominates him is to steady himself in his seat. He grasps the wheel with his whole strength. His arms stiffen, and he is as likely to steer off the road as along it. Simultaneously, and as part of the same nervous and muscular complex, he performs another act so instinctive that in most cases he is entirely unconscious of it. His legs are forcibly extended and his feet are pressed down hard. It is the muscular act

that Sherrington, who discovered it in the dog, named the "extensor thrust."

It is thus obvious that in drivers it will result in sudden hard pressure on the accelerator pedal. Since it is impossible to change this reflex, which may occur following an initial jolt or even a mental start. some other means of preventing this type of accident must be discovered. On reviewing a considerable number of accidents, Henderson feels that at least 10 per cent are due to the initiation of this reflex. It is characteristic that the thrust occurs in both legs and hence a clue to the necessary safety measures is readily available. There are some obvious disadvantages in introducing a method by which heavy pressure on the accelerator pedal will close the throttle and slow the car rather than speed it up.

There are no similar objections, however, to the introduction of a safety factor under the left foot which on a similar extensor thrust would counteract the tendency to acceleration caused by the right foot. A pedal under the left foot would involve no great difficulties of adjustment for those already accustomed to driving. It would, however, introduce an added factor of safety, which might result in a material decrease in road

accidents.

THE PLACE OF NEUROPSYCHIATRY IN A GENERAL HOSPITAL

JOHN L ECKEL, M D, Buffalo

For the purpose of a clear understanding from the start in reference to what we believe is the place of neuropsychiatry in a general hospital, I feel that a definition of our subject is in order

In a general way neurology comprises the study of all that concerns the nervous system both in health and in disease This includes those forces relating to its development or structure, its normal function, or the many deviations produced in its function or structure as a result Thus, in such an assumption, we include not only the conditions associated with anatomic changes but also those presenting a deviation from what generally accepted as the normal physiologic activity of the nervous system, which is regarded as a neurosis further includes those conditions resulting in a disturbed state of consciousness in which there is difficulty or complete mability in adapting one's self to his environment, which we regard as a psychosis

In the light of this conception it is quite patent that neurology and psychiatry are regarded as being so interwoven that no logical division can or should be made between them, hence, our use of the term, "neuropsychuatry" rather than that of neurology or psychiatry separately

Since the World War in particular, there has been a greater tendency to study each patient examined as an individual, so as to get a clear conception of what are his troubles, rather than to pigeon-hole him as such and such a disease, as has too often occurred in the past procedure resulted in directing treatment to an entity rather than to have made it individualistic as it should have been the past, too great an emphasis was placed upon the physical signs and laboratory data of all kinds rather than including the emotional make up of the patient in helping to evaluate his complaints inclination to pass over lightly the many complaints of ward patients, particularly if they are inclined to be irritable, fault finding or annoying, may lead to many errors of diagnosis and faulty treatment

It is for this type of patient as well as presenting definitely psychotic symptoms, that the assistance of a welltrained neuropsychiatrist can be of very great help in evaluating some of these complex mechanisms. There should be perfect teamwork in any general hospital among the various services and specialties, in order to give the patient the greatest opportunity for correct diagnosis and treatment

When one considers that neuropsychiatry is dealing with the dominant system controlling all the other body systems, and hence over all the essential functions of life, it must be evident that it has a very close relationship with every other field of medicine It is of special assistance to the internist in evaluating many complex situations, particularly those in reference to the various painful states, especially those of the abdomen when they may not be accompanied by any demonstrable pathology as shown by laboratory examinations, physical signs, by the roentgenologist analysis of the emotional reactions in this type of case very frequently explains the gastric distress or multiplicity of other disturbing symptoms

Often one finds the starting point of a chain of these symptoms as the result of an ill timed remark by some physician. who, in his desire to clarify his opinion, may state too much about the presence of an organic condition This is particularly true of cardiac cases, many of them with no lesion or at most a debatable, slight organic finding who have become serious invalids due to the fear caused by the knowledge of some advanced cases, or to newspaper reports of sudden deaths from heart disease

We often find a very serious neurosis associated with those who happen to know they have an increased blood pressure or some thickened vessels, which takes the form of fear of angina, cerebral hemorrhage or of sudden death A word of warning might be sounded here to those who do bedside teaching. If we would but constantly keep in mind that all sick

people are more or less suggestible, then we shall be more cautious as to what we remark before them in addressing our students. Frequently we have seen ward cases grow rapidly worse and become deeply depressed or show great anxiety, which, upon analysis was found to have been caused by the misinterpretation or exaggeration of some rather tactless remark made by a bedside teacher. This is particularly true of diseases pertaining to the circulatory system. It is wellknown that depressions, especially, are often associated with visceral and somatic disturbances which may simulate the various organic diseases affecting those organs. Any prolonged psychic emotional conflict may be the beginning of some bodily disorder, which may be expressed in the individual by such conditions as palpitation, sweating, pallor, gastric distress or vague muscle pains.

When conflicts are deeply rooted and no adequate reaction can be obtained because of the individual's constant repression of the irritating material, one frequently observes a transference of these processes into some physical or mental syndrome, such as bizarre types of anesthesia of a limb, hemianesthesia, functional paralysis, deafness, blindness or aphonia, as physical symptoms, while great anxiety states, compulsive ideas or obsessions, may represent the mental transference.

During the past few years in particular, owing in part to the economic depression, many conditions have arisen which are simulating closely the various physical conditions, but which, on careful analysis by both internist and neuropsychiatrist, are really found to have an emotional When such cases as these, commonly known as psychoneuroses, are definitely found to have no physical basis for the complaints made, they are best treated apart from other ward patients. They should be placed in a rest home or a special division of the hospital, or in some sanitarium especially devised for their treatment. They do not, as a rule, fit in long with ward routine, being inclined to be of a disturbing nature upon the slightest provocation. The benefit of a general hospital residence to such a patient, however, is the reassurance he has had from a complete physical study.

In the field of surgery, similar con-

ditions exist which are baffling at times to both the surgeon and to the neuro-In abdominal conditions psychiatrist. especially, one must continually be on the alert for an early tabes and early spinal cord disease, as well as emotional factors in evaluating other complex cases. I have had a number of opportunities to observe cases in the wards who had complaints in reference to an ankle, a knee or a leg giving out at times while walking, which condition would be associated with pain. In a few of these there was history of some minor injury, usually not sufficient to lay the patient up and usually there was no litigation in the case. In each instance, after ruling out any fundamental physical disorder, the emotional sphere was analyzed, and each time a fear of some resultant damage was elicited which showed some transference in the way of a moderate diminution of skin sensation, either of a foot, about the knee, or of the whole limb. In many instances one had to test carefully to find this diminution, as it was very slight. When a full explanation of the relationship was made, the case invariably cleared up and no symptoms remained.

The ophthomologist meets many cases where the combined study yields very fruitful results. This is especially true of early brain tumor cases, or in other conditions where a debatable eyeground change is noted. Again, in helping to solve some of the difficulties in vision in markedly suggestible individuals without demonstrable pathology, we frequently observe a strong emotional impression in the way of a fear resulting from seeing something distressing, either pertaining to the patient himself or to an intimate friend, or following some trivial injury to or about the eye. Careful sensory tests plus careful color field examination clarifies the case, and after a full explanation the symptoms disappear.

The same may be said for the otologist. Many deeply rooted emotional states manifest themselves through disturbances of hearing of the functional type. The gynecologist and urologist also furnish a wealth of material for combined study. Of interest in the fields of gynecology and urology is the fact of the tremendous interest many people manifest in their genital apparatus. Those inclined to be

introspective and suggestible, and there are many of these, fix their minds on these organs; they are unable to prevent thinking of such ideas, and soon begin to exaggerate their feelings. In this way, symptoms of what are minor disorders that would escape the notice of individuals with other interests, become exaggerated to the patient, frequently to the exclusion some other serious concomitant pathological change in other parts of the Vast numbers of these people present all types of transference resulting from some real or repressed sex aberration that only psychopathology unravel.

So it is for all fields of medicine, and it is my belief that if the specialists in the various branches of medicine would but familiarize themselves with the opportunities and advances resulting from the study of the psychic factors in the production of many disease syndromes, it would very often affect their treatment most favorably.

All this tends to argue for the need of a clear relationship between the various specialties and neuropsychiatry; also for the better opportunity in most general hospitals for the proper study of all such complex cases, for it is only by such methods that diagnostic errors can be greatly reduced. The various specialties will thus be functioning to the advancement of medicine and the cure of the

patient.

With reference to the clear-cut psychotic cases in a general hospital, I feel that in a general way there should be some provision made for them, although I admit the disadvantages in having this type of case in all such hospitals. In a hospital where there is no provision for these cases as they develop following operations, confinement, or from some other condition-and there is no other institution in the city for the care of the patient-then several rooms in some part of the hospital should be set aside. There should be proper equipment in the way of screened windows, opportunity for locking doors, continuous baths, and a trained personnel to care for them. At this time a fair number of cities have arranged for one hospital, usually a City hospital, to care for psychotic cases; and to study and treat them in conjunction with other departments of the hospital. instead of each general hospital having such a department. In this way the expense of maintaining such a department in the other hospitals is eliminated and one hospital is able to have the proper equipment and personnel. In the event that a medical school is in association with such a hospital, the teaching advantages from every standpoint cannot be overestimated.

Such a division in a general hospital affords the opportunity for early diagnosis in incipient cases, for the patient goes without prejudice or feelings of guilt or shame to a general hospital, instead of having the feeling that he has been sent to an institution for mental diseases. This fact greatly allays his worries and assures him of further careful study from every standpoint, which is always a great satisfaction not only to the patient and his family, but to his physician as well. Through such an arrangement most of the mild psychotic cases recover and thus never have the imagined stigma of a State Hospital attached to them. severer ones are studied sufficiently long so that the family can easily be persuaded to commit them, and thus save again a lot of prejudice regarding the status of a mental hospital.

In summary it might be emphasized that the field of neuropsychiatry in a general hospital is a broad one; it involves the training of special men for the work, and how to meet the different neuropsychiatric situations as they occur in different disease

pictures.

It is the opinion of C. Macfie Campbell,1 in which I concur, that in the ordinary run of ailments in any branch of medicine. which do not involve personal matters, the patient has a reasonable opportunity for systematic and efficient study and treatment. However, in those cases where the instinctive emotional and personal factors play a role, the case is likely to receive inadequate study and treatment. The neglect of personal factors in all fields of medicine is largely due to prejudice in favor of the procedures of the laboratory. Treatment and prevention have been thought of largely in terms of the metabolic and bacteriologic laboratory, The limits of these procedures are beginning to be realized, and the needs of the

JULIN L. EUNLL

patient himself, as opposed to the needs merely of his tissues and organs and systems, are coming to be studied.

Mental diseases and severe nervous conflicts may require prolonged analysis by expert workers to fathom their problem, but the effort will frequently save serious operations or other prolonged medical treatments in hospitals.

"TOO MUCH BIRTH/CONTROL BALLYHOO"

Voluntary health insurance for workers of restricted income and the liberalization of laws relating to birth control and abortion were advocated at a meeting of the Medical Society of the County of New York, at the New York Academy of Medicine, by Dr. Charles Everett Farr in his inaugural address as incoming president of the county society, on Jan. 27.

Dr. Farr discussed mercy killings, workmen's compensation, home relief, medical care, and hospitals, making it clear, however, that he was merely stating his personal views, which are "not in any way to be considered the official views of the

County Medical Society."

Dr. Farr expressed the view that while no physician has the right to commit any positive act that would shorten a patient's life, he does have the right to refrain from applying remedies that would result only in the needless prolongation of suffering, if the patient expressly states that he realizes his condition and that he no longer wishes to have his life artificially prolonged. In such cases, Dr. Farr said, the physician should have the right to allow nature to take its course.

"There has been altogether too much ballyhoo about birth control," Dr. Farr said. "The publicity methods employed have alienated many sincere physicians. Moreover, a very large element of our profession, through their deepest religious feelings, are strongly opposed to the movement.

"My own view is that while each physician should be his own judge in the matter, the law should not prohibit us from giving such advice as we see fit to those adults who ask for it. After all, they also must

choose their own way of living."

On abortions Dr. Farr said: "The evil of criminal abortions is widely known. Possibly its wake of maiming and death, if truly exposed, would closely rival that of the automobile. Surely such a condition demands a remedy.

"Birth control is a partial answer. The liberalizing of sentiment against performing abortions is another. My one thought is for the unwanted and unloved child, to be raised in poverty and ignorance, cannon fodder to be sacrificed by, or to, our modern tyrants. These do not advocate birth control."

On mercy killings, known medically as euthanasia, Dr. Farr said: "Euthanasia can be dismissed in a few words. We all want it for ourselves when the time comes, but who of us care to hold the cup of hemlock to the patient's lips? Prolongation of suffering needlessly is one thing, but the deliberate snuffing out of the vital spark is quite another."

A BOUQUET FOR THE PROFESSION NOTED IN DEATH RATE DECLINE

The death rate in the State last year was 10.8 per thousand population, the lowest in half a century, the Department of Health reports.

Almost three-quarters of the deaths in 1935 were due to heart-disease, cancer, pneumonia, nephritis, cerebral hemorrhages,

accidents and tuberculosis.

New minimum death rates were established for typhoid fever, diphtheria, infantile diarrhea, influenza, pneumonia, bronchitis, tuberculosis and accidents. Infant and maternal mortality have not been lower in the years of which there is a record and the death rates for appendicitis, suicide, homicide, alcoholism and automobile accidents were exceptionally low.

The birth rate, decreasing since 1914, reached its lowest point in 1935 at 13.5 per 1,000 population. Compared with 1934, the births decreased by less than 1,500. The corresponding reduction in 1933 was around

11,000.

SHE CARVES TOO

A doctor's wife, Mrs. Martha S. Larsson, of Detroit, has been awarded second prize in a competition for a design for a memorial fountain to be erected on Belle Isle, near that city. Mrs. Larsson studied art in Sweden and graduated from the Technical School of Arts in Stockholm. For the past three years she has been a pupil of Milles, internationally famous sculptor. Mrs. Larsson has exhibited sculptural work at the Michigan Artists' Show annually for the past eight years, but this contest was her first important competitive effort.

ROENTGENOGRAPHIC EXAMINATION OF THE LUNGS Relationship of Certain Technical Factors

CHARLES C McCoy, M D, Cooperstown

In considering what technical procedure to follow in the production of roentgenograms of the lungs in living patients, it would seem of prime importance to determine and evaluate the relationships which exist between those properties which seem to determine quality in the completed roentgenogram, and those factors which are or may be employed in its production. In attempting to visualize these relationships we have found the use of diagrams somewhat helpful We are venturing to present some of these diagrams to depict the viewpoint of one individual who is groping toward what he hopes is a better understanding of the problems involved in the roentgenographic examination of the lungs for any appreciation of the subject that we may have, we are indebted particularly to an article by Files¹ which appeared in 1931, and to the several admirable reports of Wilsey* 8 which have appeared since then

Quality in a roentgenogram, as an abstract entity, is difficult to analyze The properties of the completed roentgenogram which are frequently considered in judging its quality are detail, distortion, contrast, and density 9 10 Definition or sharpness may well be separated from detail, and regarded as a separate attribute of quality These properties have rather generally accepted but not clearly delimited meanings They are ordinarily defined in terms of their manifestation in the visual examination of the roentgeno giam but may be interpreted in terms of the factors which control their production and variation, or perhaps by some mathematical appraisal such as Thoraeus11 has employed in defining geometrical sharpness

Detail is a rather inclusive term, which is largely self explaintory, it is usually considered to be the most important element of quality. Definition is perhaps a more pleasing designation than sharpness for that characteristic which is probably somewhat more accurately depicted by the latter word. Distortion refers to the

deviation of the images of objects in the roentgenogram from the true shapes and sizes of the objects, distortion with respect to shape will not be considered further in this discussion, distortion with respect to size or magnified distortion might possibly be more precisely designated as magnification Wilsey apparently uses magnification to refer to the enlargement of a single object or part, and reserves distortion to refer only to variations in magnification. We will use distortion to refer to any magnification Density relates to the degree of blackening of the roentgenogram as a whole Contrast refers to the differences in density between different areas

There appear to be various relationships among definition, distortion, contrast, de-tail, and density Wilsey states that detail is the result of definition and contrast, others regard distortion as also playing an important role in detail Definition or sharpness is certainly closely related to and an essential constituent of detail, and an increase in definition tends to produce an increase in detail Contrast, likewise, seems closely related to and an essential constituent of detail, within certain limits an increase in contrast occasions an enhancement of detail, with sufficient increase in contrast, however, certain areas of the roentgenogram may attain such extremes of density that the detail in them is not apparent. If the concept of detail includes the portrayal of dimensions as accurately as possible, as I think it should. then it follows that the minimizing of magnified distortion leads to an increase of detail There seems to be a certain slight but definite symbiotic association between definition and contrast, as judged by the eye, the sharpness of the line of demarcation between two adjoining areas appears to be increased if the contrast between the two areas be enhanced, and, conversely, the contrast between two adjoining areas seems to be augmented if the sharpness of the line of demarcation between them be increased Definition and

distortion are separate properties of the roentgenogram but seem somewhat related; both may be regarded as relating to size; both are influenced by the factors of distance (object-film and focal-film); and increase in one tends to be associated with a decrease in the other, although this association does not necessarily occur. In order to recognize this apparent association it will be assumed that distortion embraces all properties of the roentgenogram that are affected by the relationship between object-film distance and focal-film distance; from this assumption it may be inferred that a decrease in distortion tends to effect an accentuation of definition. The visibility of contrast and detail depends upon density; there is usually a rather wide range of density within which both contrast and detail are readily apparent; but with either too great or too little density, their visibility is lessened.

Figure 1 represents an attempt to portray diagrammatically certain of the relationships or trends that seem, or have been assumed, to exist between these characteristics of the roentgenogram which have been considered. A plus sign adjacent to the name of a characteristic denotes an increase in that characteristic: a minus sign signifies a decrease; two plus or two minus signs indicate a marked increase and marked decrease, respectively. The lines between the names of the characteristics show the trends considered and the arrow at the end of each line indicates the direction of its trend. Thus, an increase in definition tends to produce an increase in detail (trend 1). A decrease in distortion likewise tends to enhance detail (trend 2) and also to increase definition (trend 9). An increase in contract tends to increase detail (trend 3) but a too greatly increased contrast

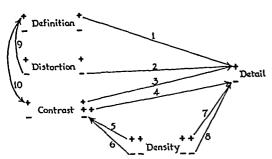

Fig. 1. Relationship assumed to exist between the properties of quality in the roentgenogram.

tends to diminish detail (trend 4). A greatly increased density tends to effect a diminution in both contrast and detail (trends 5 and 7) as does also a greatly diminished density (trends 6 and 8). The mutually augmenting relationship between increases of definition and contrast is indicated by trend 10.

We will assume, that the quality of a roentgenogram is governed by its definition, distortion, contrast, detail, and density; that the composite element of detail is the most important of these; and that, in the quest for quality, the attainment of greater detail while maintaining a density sufficient to visualize satisfactorily that detail is the most important consideration.

The principal factors to be considered in the production of roentgenograms of the lungs may, I think, be rather conveniently viewed in five groups, as follows:

1. The fundamental factors of exposure. These are voltage, milliamperage, time of exposure, and distance (focal-film or anodefilm). These are the factors commonly employed in describing roentgenographic technic and are fundamental, in that no roentgenographic exposure can be made without them. These four factors may all be varied with the limits of their variation determined by the capacity of the x-ray apparatus, which is available for use.

2. Certain accessory or mechanical factors. These include the x-ray tube, intensifying screens, cones, diaphragms, the Potter-Bucky diaphragm and filters. The x-ray tube has many characteristics, of which probably the most important is the size of its focal spot. Intensifying screens likewise have several characteristics, such as speed and grain. This is a rather flexible group in which the operator ordinarily has considerable freedom in selection.

3. Certain factors relating to the patient. In this category there is placed the movement of and within the patient, the distance of the patient from the roentgen-film (object-film distance) the scattered radiation arising in the patient, the size and musculature of the chest, the amount and nature of the intrathoracic pathology if there be any, and the cooperation of the patient during the examination. The factors relating to the patient constitute the most inflexible group with which the roentgenologist has to deal.

4. Factors associated with the film. These include such properties as the speed

and contrast of the film. They will not be considered further since their control is largely beyond the realm of the roent-

genologist.

5. Processing factors. This group embraces the factors concerned with the procedures in the dark-room, such as the composition of the solutions employed, their strength and temperature, and the time of These factors are of major development. importance in determining roentgenographic quality but will not be considered further in this discussion.

The control of the quality of the completed roentgenogram rests in the utilization and manipulation of these various factors concerned in its production. Roentgenograms of satisfactory diagnostic value may be obtained by a variety of technical procedures, and what constitutes the most satisfactory roentgenogram is a matter of opinion. But if the attempted analysis of the elements constituting quality which has been presented, possesses a moderate degree of validity; it follows that the control of definition, distortion, contrast, and density are essential to the control of quality; it follows also, that, in a general way, the aim should be to secure as much definition or sharpness as possible, to obtain the minimum amount of distortion possible, to obtain as much contrast as can be had without losing detail, and to have a density that permits the satisfactory visualization of the contrast and the detail.

We will endeavor to portray diagrammatically some of the relationships that seem to arise between these factors which have been assumed to establish quality and the factors of production, when one attempts to vary certain intensities of the factors of quality. The relationships depicted do not represent all that exist; they are presented as trends or tendencies without definite quantitative value, so that if the portrayal has any merit, it is in visualizing the problems involved, and not in solving them. The trends selected are shown by lines in which an arrow indicates the direction of the trend; a plus sign adjacent to the name of a factor indicates an increase in that factor while a minus sign indicates a decrease: the factors relating to the roentgenogram are placed at the left; the fundamental factors of exposure are at the right; those factors which have been designated mechanical or accessory are at the top; and the factors relating to the patient are placed at the bottom.

The variations thus considered are: (1) Increasing definition by decreasing the effect of motion; (2) increasing definition by decreasing the size of the focal spot of the tube; (3) decreasing distortion; (4) increasing contrast, explained in the following:

1. Increasing definition by decreasing the effect of motion. Motion of and within the patient is probably the most important single factor to be considered in the roentgenographic examination of the lungs; it is potentially the most important factor in the control of definition or sharpness. general way, one may assume that the amount of blurring or unsharpness produced in the roentgenogram by movement varies directly with the rate of the movement and with the duration of the exposure. Thus, it would seem that if the movement itself cannot be eliminated, its effect may be mitigated by shortening the time of

exposure.

Figure 2 indicates some of the relationships that may be considered when one attempts to obtain an increase in definition by means of a decrease in the effect of motion (trend 1). Shortening the time of exposure is the most important factor in effecting a decrease in the effect of motion (trend 2). Probably the chief factor to permit a decrease in the time of exposure is the use of intensifying screens (trend 3); the use of screens, however, causes a certain decrease in the definition (trend 4) and, ordinarily, the greater the speed of the screens the greater is the decrease in the definition. Thus the mechanical factor of intensifying screens exerts indirectly an augmenting and directly a decreasing effect

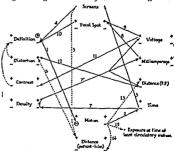

Fig. 2. Increasing definition by decreasing the effect of motion.

upon the property of definition; the former influence is probably much the greater. Also, the use of screens with casettes and a casette holder has a tendency to slightly increase the distance between the patient and film, and in so doing to increase the property of distortion (trends 5 and 6). creasing the time of exposure in order to lessen the effect of motion tends to diminish the density (trend 7); but density has to be maintained within a certain range in order to secure a satisfactory roentgenogram, and this tendency for its diminution necessitates consideration of a compensatory augmentation of the density by means of one or more of the other factors controlling it. This augmentation may be obtained through an increase in voltage, an increase in milliamperage, a decrease in the focalfilm distance or through a combination of these (trend 7). If either voltage or milliamperage, or both, are increased, the production of heat at the anode of the tube is increased, which tends to necessitate a larger focal spot (trends 8 and 9). As the size of the focal spot used is increased, the definition decreases (trend 10). The last is a relationship of major significance; the quest for ultra-rapid exposures may be of doubtful merit when it entails greatly increasing the size of the focal spot employed. Also, an increase of voltage to compensate for diminution in density tends to produce a loss of contrast (trend 11), which may occasion a small loss in definition. The relationships between voltage and milliamperage vary with the x-ray machine employed; possibly the most significant is a tendency for an increase in milliamperage to occasion a drop in voltage. If a decrease in the focal-film distance be employed in combating diminished density, distortion is increased (trend 12) and through it definition may be lessened.
